Preface

This chapter provides information about this documentation set. The sections are as follows.

- Related Products (p. x) MathWorks products related to the Compiler
- Using this Guide (p. xi) An overview of this book
- Typographical Conventions (p. xii) Typographical conventions used in this book
Related Products

The MATLAB Compiler automatically converts MATLAB M-files to C and C++ code. The MATLAB Compiler includes the MATLAB C/C++ Math and Graphics Libraries, which let you automatically convert your MATLAB applications to C and C++ code for stand-alone applications.

The MathWorks provides several products that are especially relevant to the MATLAB Compiler. For more information about any of these products, see either

- The online documentation for that product

Using this Guide

This book describes the MATLAB Compiler and provides numerous examples of how to use it. The topics included are

- Introducing the MATLAB Compiler — describes the new features of the Compiler and provides an overview of how to use it.
- Installation and Configuration — discusses how to install and configure the Compiler, and how to verify that your system is properly set up.
- Working with MEX-Files — describes how to compile M-files with the MATLAB Compiler.
- Stand-Alone Applications — explains how to use the MATLAB Compiler to code and build stand-alone applications.
- Controlling Code Generation — describes the code generated by the MATLAB Compiler and the options that you can use to control code generation.
- Optimizing Performance — describes optimizations you can perform on your M-file source code that can improve the performance of the generated C/C++ code.
- Reference — provides the set of reference pages that describe the Compiler pragmas, functions, and command line tools.
- MATLAB Compiler Quick Reference — is a quick reference of all the Compiler functions.
- Error and Warning Messages — lists and describes error messages and warnings generated by the MATLAB Compiler.
Typographical Conventions

This manual uses some or all of these conventions.

Introduction

This book describes Version 3.0 of the MATLAB® Compiler. The MATLAB Compiler takes M-files as input and generates C or C++ source code or P-code as output. The MATLAB Compiler can generate these kinds of source code:

- C source code for building MEX-files.
- C or C++ source code for combining with other modules to form stand-alone applications. Stand-alone applications do not require MATLAB at run-time; they can run even if MATLAB is not installed on the end-user’s system.
- C code S-functions for use with Simulink®.
- C shared libraries (dynamically linked libraries, or DLLs, on Microsoft Windows) and C++ static libraries. These can be used without MATLAB on the end-user’s system.
- Excel compatible plug-ins
- COM (Component Object Model) objects.

This chapter takes a closer look at these categories of C and C++ source code and explains the value of compiled code.

**Note** MATLAB Compiler 3.0 includes the MATLAB C/C++ Math Library and the MATLAB C/C++ Graphics Library. Installing the MATLAB Compiler automatically installs the C/C++ Math and Graphics Libraries.

**Before You Begin**

Before reading this book, you should already be comfortable writing M-files. If you are not, see Programming and Data Types in the MATLAB documentation.
**Note** The phrase *MATLAB interpreter* refers to the application that accepts MATLAB commands, executes M-files and MEX-files, and behaves as described in the Using MATLAB documentation. When you use MATLAB, you are using the MATLAB interpreter. The phrase *MATLAB Compiler* refers to this product, which translates M-files to C or C++ source code and its associated libraries. This book distinguishes references to the MATLAB Compiler by using the word ‘Compiler’ with a capital C. References to “compiler” with a lowercase c refer to your C or C++ compiler.
New Features

MATLAB Compiler 3.0

- The MATLAB Compiler now includes the MATLAB C/C++ Math and Graphics Libraries.

**Note** As the MATLAB Compiler evolves, it will support additional standard platform interfaces such as COM, Java, and CORBA. Consequently, the requirement of developing code specifically for the MATLAB C/C++ Math Library will diminish. Once this happens, the Math Library will no longer support code written directly for the Library. The Compiler will continue to use the MATLAB C/C++ Math Library as it currently does.

- A new optimization is available that allows the Compiler to use simpler types for variables at run-time, when possible. For more information about this optimization, see Chapter 6, “Optimizing Performance.”
- The MATLAB Compiler allows you to create COM components from MATLAB M-files.

**Note** To create COM components with the MATLAB Compiler, you must have the MATLAB COM Builder product installed on your system.

MATLAB Compiler 2.3

MATLAB Compiler 2.3 allows you to create Microsoft Excel components from MATLAB M-files. This Windows-only feature translates a collection of M-files into a single Microsoft Excel add-in. Both C and C++ code generation are supported.

To support the creation of these components, the following Compiler options have been added or enhanced:

- The bundle option (-B) has been enhanced so that you can include replacement parameters for Compiler options that accept names and version numbers and they will be expanded properly.
The new option, -b, causes the Compiler to generate a Visual Basic (.bas) file that contains the Microsoft Excel Formula Function interface to a Compiler-generated COM object.

The new option, -i, causes the Compiler to include only the M-files that are specified on the command line as exported interfaces.

**Note** To create Microsoft Excel components with the MATLAB Compiler, you must have the MATLAB Excel Builder product installed on your system.

**MATLAB Compiler 2.1**
MATLAB Compiler 2.1 supports much of the functionality of MATLAB 6. The new features of the Compiler are

- Optimizations
- mlib files
- Additional data type support
- Improved support for load and save
- Dynamically linking in MEX-files in the stand-alone environment
- MATLAB add-in for Visual Studio
- Faster C/C++ Math Library applications
- Additional language support

**Optimizations**
The MATLAB Compiler provides a series of optimizations that can help speed up your compiled code. These optimizations are on by default unless you are building a debuggable version.

**Folding Array Constants.** Folds scalar and nonscalar valued array constants.

**One- and Two-Dimensional Array Indexing.** Uses faster routines that are optimized for simple indexing.

**for-loops.** Optimizes for-loops with integer starts and increments.
Conditional Expressions. Reduces the MATLAB conditional operators to scalar C conditional operators when both operands are known to be integer scalars.

For more information on these optimizations, see Chapter 6, “Optimizing Performance.”

mlib Files

mlib files make it possible to produce a shared library out of a toolbox and then compile M-files that make calls into that toolbox. Specifying an mlib file tells the MATLAB Compiler to link against the mlib file’s corresponding shared library whenever it needs to use any of the functions found in that library. The mlib file and its corresponding shared library file must be located within the same directory. For more information about mlib files, see “mlib Files” on page 5-26.

Additional Data Type Support

Integer Data Types. The signed and unsigned integer arrays int8, int16, int32, uint8, uint16, and uint32 are now supported, which provides improved support for the Image Processing Toolbox.

Function Handles. A function handle is a new MATLAB data type that captures all the information about a function that MATLAB needs to evaluate it. The MATLAB Compiler supports function handles. For more information on function handles, see the function handle reference page.

Improved Support for load and save

load and save are now supported when they do not list the variables to be loaded or saved. They work by loading or saving all variables that are defined or used within the function.

Dynamically Linking in MEX-Files in the Stand-Alone Environment

Specifying -h or providing the name of a function on the command line will automatically link in any referenced MEX-files.

MATLAB Add-In for Visual Studio®

This add-in integrates the MATLAB Compiler into Visual C/C++ Version 5 or 6. To learn more about the MATLAB add-in for Visual Studio, see “Using an Integrated Development Environment” on page 4-23.
Faster C/C++ Math Library Applications

The improved performance of the C/C++ Math Library is due in part to the added scalar accelerated versions of many of the library functions.

Additional Language Support

pause and continue. These commands are now supported.

eval and input. eval and input are supported for strings that do not contain workspace variables.

Note As of Compiler 2.1, Compiler 1.2 is no longer available due to the evolution of internal data structures. The -V1.2 option is no longer supported, along with any options recognized by Compiler 1.2.

Compiler Licensing Changes

Starting with Compiler 1.2.1, a new licensing scheme has been employed that enables the product to be simpler and more user friendly.

In versions prior to 1.2.1, you could not run the MATLAB Compiler unless you were running MATLAB. On networked systems, this meant that one user would be holding the license for one copy of MATLAB and the Compiler, simultaneously. In effect, one user required both products and tied up both licenses until the user exited MATLAB. Although you can still run the Compiler from within MATLAB, it is not required. One user could be running the Compiler while another user could be using MATLAB.

The licensing model is based on how you run the Compiler:

• From the MATLAB command prompt
• From a DOS/UNIX shell

Running Compiler from MATLAB

When you run the Compiler from “inside” of MATLAB, that is, you run mcc from the MATLAB command prompt, you hold the Compiler license as long as MATLAB remains open. To give up the Compiler license, exit MATLAB.
Introducing the MATLAB Compiler

Running Compiler from DOS/UNIX Shell
If you run the Compiler from a DOS or UNIX shell, you are running from “outside” of MATLAB. In this case, the Compiler

• Does not require MATLAB to be running on the system where the Compiler is running
• Gives the user a dedicated 30 minute allotment during which the user has complete ownership over a license to the Compiler

Each time a user requests the Compiler, the user begins a 30 minute time period as the sole owner of the Compiler license. Anytime during the 30 minute segment, if the same user requests the Compiler, the user gets a new 30 minute allotment. When the 30-minute time interval has elapsed, if a different user requests the Compiler, the new user gets the next 30 minute interval.

When a user requests the Compiler and a license is not available, the user receives the message

    Error: Could not check out a Compiler License.

This message is given when no licenses are available. As long as licenses are available, the user gets the license and no message is displayed. The best way to guarantee that all MATLAB Compiler users have constant access to the Compiler is to have an adequate supply of licenses for your users.
Uses of the Compiler

The MATLAB Compiler (mcc) can translate M-files into C files. The resultant C files can be used in any of the supported executable types including MEX, executable, or library by generating an appropriate wrapper file. A wrapper file contains the required interface between the Compiler-generated code and a supported executable type. For example, a MEX wrapper contains the MEX gateway routine that sets up the left- and right-hand arguments for invoking the Compiler-generated code.

The code produced by the MATLAB Compiler is independent of the final target type — MEX, executable, or library. The wrapper file provides the necessary interface to the target type.

Note MEX-files generated by the MATLAB Compiler are not backward compatible.

Creating MEX-Files

The MATLAB Compiler, when invoked with the -x macro option, produces a MEX-file from M-files. The Compiler

1 Translates your M code to C code.

2 Generates a MEX wrapper.

3 Invokes the mex utility which builds the C MEX-file source into a MEX-file by linking the MEX-file with the MEX version of the math libraries (libmatlbmx).

Figure 1-1, Developing MEX-Files, illustrates the process of producing a MEX-file. The MATLAB interpreter dynamically loads MEX-files as they are needed.
Introducing the MATLAB Compiler

Figure 1-1: Developing MEX-Files

MATLAB users who do not have the MATLAB Compiler must write the source code for MEX-files in either Fortran or C. “External Interfaces/API” in the MATLAB documentation explains the fundamentals of this process. To write MEX-files, you have to know how MATLAB represents its supported data types and the MATLAB external interface (i.e., the application program interface, or API.)

If you are comfortable writing M-files and have the MATLAB Compiler, then you do not have to learn all the details involved in writing MEX-file source code.
Creating Stand-Alone Applications

C Stand-Alone Applications
The MATLAB Compiler, when invoked with the `-m` macro option, translates input M-files into C source code that is usable in any of the supported executable types. The Compiler also produces the required wrapper file suitable for a stand-alone application. Then, your ANSI C compiler compiles these C source code files and the resulting object files are linked against the MATLAB C/C++ Math and Graphics Libraries, which are included with the MATLAB Compiler. For more information about distributing a C application, see “Distributing Stand-Alone Applications” on page 4-27.

C++ Stand-Alone Applications
The MATLAB Compiler, when invoked with the `-p` macro option, translates input M-files into C++ source code that is usable in any of the executable types except MEX. The Compiler also produces the required wrapper file suitable for a stand-alone application. Then, your C++ compiler compiles this C++ source code and the resulting object files are linked against the MATLAB C/C++ Math and Graphics Libraries, which are included with the MATLAB Compiler. For more information about which libraries must be included when you distribute a C++ application, see “Distributing Stand-Alone Applications” on page 4-27.

Developing a Stand-Alone Application
Suppose you want to create an application that calculates the rank of a large magic square. One way to create this application is to code the whole application in C or C++; however, this would require writing your own magic square, rank, and singular value routines.

An easier way to create this application is to write it as one or more M-files. Figure 1-2, Developing a Typical Stand-Alone C Application, outlines this development process.
Introducing the MATLAB Compiler

Figure 1-2: Developing a Typical Stand-Alone C Application
See Chapter 4, “Stand-Alone Applications” for complete details regarding stand-alone applications.

Figure 1-2, Developing a Typical Stand-Alone C Application, illustrates the process of developing a typical stand-alone C application. Use the same basic process for developing stand-alone C++ applications, but use the -p option instead of the -m option with the MATLAB Compiler and a C++ compiler instead of a C compiler.

**Note** The MATLAB Compiler contains a tool, mbuild, which simplifies much of this process. Chapter 4, “Stand-Alone Applications” describes the mbuild tool.

-p and -m are examples of options that you use to control how the Compiler works. Chapter 7, “Reference,” includes a complete description of the Compiler options in the mcc section. Throughout this book you will see numerous examples of how these options are used with the Compiler to perform various tasks.
The MATLAB Compiler Family

This figure illustrates the various ways you can use the MATLAB Compiler. The shaded blocks represent user-written code; the unshaded blocks represent Compiler-generated code; the remaining blocks (drop shadow) represent MathWorks or other vendor tools.

Figure 1-3: MATLAB Compiler Uses
The Compiler takes your M-file(s) and can generate C or C++ code. It can also generate a wrapper file depending on your specified target. This table shows the wrapper files the Compiler can generate, their associated targets, and the corresponding `-W` option (wrapper).

### Table 1-1: Compiler Wrappers and Targets

<table>
<thead>
<tr>
<th>Wrapper File</th>
<th>Target</th>
<th>-W Setting</th>

<td>Simulink C MEX-file</td>
<td><code>-W simulink</code></td>
</tr>
</tbody>
</table>
| COM          | COM object | `-W com:<componentname>[],<classname>[,<major>.<minor>]]`  
               |         | `-W comhg:<componentname>[],<classname>[,<major>.<minor>]]` |
| Excel        | Excel Plug-in | `-W excel:<componentname>[],<classname>[,<major>.<minor>]]`  
               |         | `-W excelhg:<componentname>[],<classname>[,<major>.<minor>]]` |

Each numbered node in Figure 1-3, MATLAB Compiler Uses, indicates a combination of C/C++ code and a wrapper that generates a specific target type. The file(s) formed by combining the C/C++ code (denoted by “User C/C++ Code”) and the wrapper are then passed to the C/C++ compiler, which combines them with any user-defined C/C++ programs, and eventually links them against the appropriate libraries. The end result of this sequence is the target as described in the table above.
Why Compile M-Files?

There are several reasons to compile M-files:

- To create stand-alone applications
- To create C shared libraries (DLLs on Windows) or C++ static libraries
- To create COM components
- To hide proprietary algorithms

Stand-Alone Applications and Libraries

You can create MATLAB applications that take advantage of the mathematical functions of MATLAB, yet do not require that the user owns MATLAB. Stand-alone applications are a convenient way to package the power of MATLAB and to distribute a customized application to your users.

You can develop an algorithm in MATLAB to perform specialized calculations and use the Compiler to create a C shared library (DLL on Windows) or a C++ static library. You can then integrate the algorithm into a C/C++ application. After you compile the C/C++ application, you can use the MATLAB algorithm to perform specialized calculations from your program.

Excel Plug-Ins

With the optional MATLAB Excel Builder, you can automatically generate a Visual Basic Application file (.bas) and a plug-in DLL from your MATLAB model that can be imported into Excel as a stand-alone function.

COM Components

With the optional MATLAB COM Builder, you can create COM components that can be used in any application that works with COM objects.

Hiding Proprietary Algorithms

MATLAB M-files are ASCII text files that anyone can view and modify. MEX-files are binary files. Shipping MEX-files or stand-alone applications instead of M-files hides proprietary algorithms and prevents modification of your M-files.
Upgrading from Previous Versions of the Compiler

MATLAB Compiler 3.0 is fully compatible with previous releases of the Compiler. If you have your own M-files that were compiled with a previous version of the Compiler and compile them with the new version, you will get the same results.

Upgrading from MATLAB Compiler 2.0/2.1/2.2/2.3
MATLAB Compiler 2.1 (and later versions) does not support the -V1.2 option that was available in Compiler 2.0.

Upgrading from MATLAB Compiler 1.0/1.1
In many cases, M-code that was written and compiled in MATLAB 4.2 will work as is in the MATLAB 6 and the MATLAB 5 series. There are, however, certain changes that could impact your work, especially if you integrated Compiler-generated code into a larger application.

Changed Library Name
Beginning with MATLAB 5.0, the name of the shared library that contains compiled versions of most MATLAB M-file math routines, libtbx, has changed. The new library is now called libmmfile.

Changed Data Type Names
In C, beginning with MATLAB 5.0, the name of the basic MATLAB data type, Matrix, has changed. The new name for the data type is mxArray.

In C++, beginning with MATLAB 5.0, the name of the basic MATLAB data type, mwMatrix, has changed. The new name for the data type is mwArray.
Limitations and Restrictions

**MATLAB Code**

MATLAB Compiler 3.0 supports almost all of the functionality of MATLAB. However, there are some limitations and restrictions that you should be aware of. This version of the Compiler cannot compile

- Script M-files (See “Converting Script M-Files to Function M-Files” on page 3-10 for further details.)
- M-files that use objects
- Calls to the MATLAB Java interface
- M-files that use `input` or `eval` to manipulate workspace variables

**Note**  `input` and `eval` calls that do not use workspace variables will compile and execute properly.

- M-files that use `exist` with two input arguments, for example:
  ```matlab
  exist('foo','var')
  ```
  The single variable form works for filenames and functions only.

- M-files that dynamically name variables to be loaded or saved. This example is disallowed by the Compiler:
  ```matlab
  x = 'f';
  load('foo.mat',x);
  ```

- M-files that load text files, for example:
  ```matlab
  load -ascii sampling1
  ```

The Compiler cannot compile built-in MATLAB functions (functions such as `eig` have no M-file, so they can’t be compiled). Note, however, that most of these functions are available to you because they are in the MATLAB Math Built-in Library (`libmatlb`).

In addition, the Compiler does not honor conditional global and persistent declarations. It treats `global` and `persistent` as declarations. For example:
if (y==3)
    persistent x
else
    x = 3;
end

Stand-Alone Applications
The restrictions and limitations noted in the previous section also apply to stand-alone applications. The functions in Table 1-2, Unsupported Functions in Stand-Alone Mode, are supported in MEX-mode, but are not supported in stand-alone mode.

Note Stand-alone applications cannot access Simulink functions. Although the MATLAB Compiler can compile M-files that call these functions, the MATLAB C/C++ Math library does not support them. Therefore, unless you write your own versions of the unsupported routines in a MEX-file or as C code, when you run the executable, you will get a run-time error.

Fixing Callback Problems: Missing Functions

When the Compiler creates a stand-alone application, it compiles the M-file you specify on the command line and, in addition, it compiles any other M-files that your M-file calls. If your application includes a call to a function in a callback string or in a string passed as an argument to the `feval` function or an ODE solver, and this is the only place in your M-file this function is called, the Compiler will not compile the function. The Compiler does not look in these text strings for the names of functions to compile.

**Symptom**

Your application runs, but an interactive user interface element, such as a push button, is unresponsive. When you close the application, the graphics library issues this error message.

```
An error occurred in the callback: change_colormap
The error message caught was: Reference to unknown function change_colormap from FEVAL in stand-alone mode.
```

**Workaround**

To eliminate this error, create a list of all the functions that are specified only in callback strings and pass this list to the `%#function` pragma. (See “Finding Missing Functions in an M-File” on page 1-21 for hints about finding functions.
in callback strings.) The Compiler processes any function listed in a %#function pragma.

For example, the call to the change_colormap function in the sample application, my_test, illustrates this problem. To make sure the Compiler processes the change_colormap M-file, list the function name in the %#function pragma:

```matlab
function my_test()
  % Graphics library callback test application

  %#function change_colormap

  peaks;

  p_btn = uicontrol(gcf,...
      'style', 'pushbutton',...
      'Position', [10 10 133 25 ],...
      'String', 'Make Black & White',...
      'CallBack', 'change_colormap');
```

**Note** Instead of using the %#function pragma, you can specify the name of the missing M-file on the Compiler command line.

### Finding Missing Functions in an M-File

To find functions in your application that may need to be listed in a %#function pragma, search your M-file source code for text strings specified as callback strings or as arguments to the feval, fminbnd, fminsearch, funm, and fzero functions or any ODE solvers.

To find text strings used as callback strings, search for the characters “Callback” or “fcn” in your M-file. This will find all the Callback properties defined by Handle Graphics® objects, such as uicontrol and uimenu. In addition, this will find the properties of figures and axes that end in Fcn, such as CloseRequestFcn, that also support callbacks.
1 Introducing the MATLAB Compiler
Installation and Configuration

This chapter describes the system requirements for the MATLAB Compiler and installation and configuration information. It includes information for both MATLAB Compiler platforms — UNIX and Microsoft Windows.

When you install your ANSI C or C++ compiler, you may be required to provide specific configuration details regarding your system. This chapter contains information for each platform that can help you during this phase of the installation process. The sections, “Things to Be Aware of,” provide this information for each platform.

- System Configuration for MEX-Files (p. 2-2)  Steps to create MEX-files
- UNIX Workstation (p. 2-4)  Configuration on UNIX systems
- Microsoft Windows on PCs (p. 2-13)  Configuration on PCs
- Troubleshooting (p. 2-25)  Dealing with installation and configuration problems
System Configuration for MEX-Files

This section outlines the steps necessary to configure your system to create MEX-files.

The sequence of steps to install and configure the MATLAB Compiler so that it can generate MEX-files is

1. Install the MATLAB Compiler.
2. Install an ANSI C or C++ compiler, if you don’t already have one installed.

Note: If you encounter problems relating to the installation or use of your ANSI C or C++ compiler, consult the documentation or customer support organization of your C or C++ compiler vendor.

3. Verify that `mex` can generate MEX-files.
4. Verify that the MATLAB Compiler can generate MEX-files from the MATLAB command line and from the UNIX or DOS command line.

Figure 2-1, MATLAB Compiler Installation Sequence for Creating MEX-Files, shows the Compiler installation sequence for creating MEX-files on both platforms. The sections following the flowchart provide more specific details for the individual platforms. Additional steps may be necessary if you plan to create stand-alone applications or libraries, however, you still must perform the steps given in this chapter first. Chapter 4, “Stand-Alone Applications” provides the details about the additional installation and configuration steps necessary for creating stand-alone applications and libraries.

Note: This flowchart assumes that MATLAB is properly installed on your system.
Figure 2-1: MATLAB Compiler Installation Sequence for Creating MEX-Files
UNIX Workstation

This section examines the system requirements, installation procedures, and configuration procedures for the MATLAB Compiler on UNIX systems.

System Requirements

You cannot install the MATLAB Compiler unless MATLAB 6.5 (Release 13) is already installed on the system. The MATLAB Compiler imposes no operating system or memory requirements beyond those that are necessary to run MATLAB. The MATLAB Compiler consumes a small amount of disk space.

Table 2-1, Requirements for Creating UNIX Applications, shows the requirements for creating UNIX applications with the MATLAB Compiler.

Table 2-1: Requirements for Creating UNIX Applications

<table>
<thead>
<tr>
<th>To create...</th>
<th>You need...</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEX-files</td>
<td>ANSI C compiler</td>
</tr>
<tr>
<td></td>
<td>MATLAB Compiler</td>
</tr>
<tr>
<td>Stand-alone C applications</td>
<td>ANSI C compiler</td>
</tr>
<tr>

<td>MATLAB Compiler</td>
</tr>
<tr>
<td>Stand-alone C++ applications</td>
<td>C++ compiler</td>
</tr>
<tr>
<td></td>
<td>MATLAB Compiler</td>
</tr>
</tbody>
</table>

Note Although the MATLAB Compiler supports the creation of stand-alone C++ applications, it does not support the creation of C++ MEX-files.

Supported ANSI C and C++ UNIX Compilers

The MATLAB Compiler supports

- The GNU C compiler, gcc, (except on HP and SGI64)
- The system’s native ANSI C compiler on all UNIX platforms
- The system’s native C++ compiler on all UNIX platforms (except Linux)
- The GNU C++ compiler, g++, on Linux.
Note For a list of all the compilers supported by MATLAB, see the MathWorks Technical Support Department's Technical Notes at

Known Compiler Limitations. There are several known restrictions regarding the use of supported compilers:

- The SGI C compiler does not handle denormalized floating-point values correctly. Denormalized floating-point numbers are numbers that are greater than 0 and less than the value of DBL_MIN in the compiler’s float.h file.

- Due to a limitation of the GNU C++ compiler (g++) on Linux, try catch end blocks do not work.

- The -A debugline:on option does not work on the GNU C++ compiler (g++) on Linux because it uses try catch end.

- Some UNIX compilers produce warnings that suggest additional optimizations can be performed that might result in faster code. For example, on IBM RS/6000 systems you may see a warning message similar to 1500-030: (I) INFORMATION: Miofun_private_imgifinfo: Additional optimization may be attained by recompiling and specifying MAXMEM option with a value greater than 2048.

  See your vendor compiler documentation for more information on how to improve optimization. Normally, this involves changing compiler options. Use CFLAGS= in your mbuildopts file.

Note This compiler warning is benign and will have no harmful effect on your code.

Compiler Options Files

The MathWorks provides options files for every supported C or C++ compiler. These files contain the necessary flags and settings for the compiler. This table
shows the preconfigured options files that are included with MATLAB for UNIX.

<table>
<thead>
<tr>
<th>Compiler</th>
<th>Options File</th>
</tr>
</thead>
<tbody>
<tr>
<td>System native ANSI compiler</td>
<td>mexopts.sh</td>
</tr>
<tr>
<td>gcc (GNU C compiler)</td>
<td>gccopts.sh</td>
</tr>
</tbody>
</table>

Information on the options files is provided for those users who may need to modify them to suit their own needs. Many users never have to be concerned with the inner workings of the options files.

**Locating Options Files**
To locate your options file, the `mex` script searches the following:

- The current directory
- `$HOME/.matlab/R13`
- `<matlab>/bin`

`mex` uses the first occurrence of the options file it finds. If no options file is found, `mex` displays an error message.

**Installation**

**MATLAB Compiler**
To install the MATLAB Compiler on UNIX workstations, follow the instructions in the MATLAB Installation Guide for the UNIX platform. If you have a license to install the MATLAB Compiler, it appears as one of the installation choices that you can select as you proceed through the installation process. If the MATLAB Compiler does not appear as one of the installation choices, contact The MathWorks to get an updated license file (`license.dat`):

- Via e-mail at service@mathworks.com
ANSI C or C++ Compiler
To install your ANSI C or C++ compiler, follow the vendor’s instructions that accompany your C or C++ compiler. Be sure to test the C or C++ compiler to make sure it is installed and configured properly. Typically, the compiler vendor provides some test procedures. The following section, “Things to Be Aware of,” contains several UNIX-specific details regarding the installation and configuration of your ANSI C or C++ compiler.

**Note** On some UNIX platforms, a C or C++ compiler may already be installed. Check with your system administrator for more information.

**Things to Be Aware of**
This table provides information regarding the installation and configuration of a C or C++ compiler on your system.

<table>
<thead>
<tr>
<th>Description</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Determine which C or C++ compiler is installed on your system.</td>
<td>See your system administrator.</td>
</tr>
<tr>
<td>Determine the path to your C or C++ compiler.</td>
<td>See your system administrator.</td>
</tr>
</tbody>
</table>

**mex Verification**

**Choosing a Compiler**

**Using the System Compiler.** If the MATLAB Compiler and your supported C or C++ compiler are installed on your system, you are ready to create C MEX-files. To create a MEX-file, you can simply enter

```
mex filename.c
```

This simple method of creating MEX-files works for the majority of users. It uses the system’s compiler as your default compiler for creating C MEX-files.
If you do not need to change C or C++ compilers, or you do not need to modify your compiler options files, you can skip ahead in this section to “Creating MEX-Files” on page 2-9. If you need to know how to change the options file, continue with this section.

Changing Compilers

Changing the Default Compiler. To change your default C or C++ compiler, you select a different options file. You can do this at anytime by using the command

```
mex -setup
```

Using the 'mex -setup' command selects an options file that is placed in ~/.matlab/R13 and used by default for 'mex'. An options file in the current working directory or specified on the command line overrides the default options file in ~/.matlab/R13.

Options files control which compiler to use, the compiler and link command options, and the runtime libraries to link against.

To override the default options file, use the 'mex -f' command (see 'mex -help' for more information).

The options files available for mex are:

1: <matlab>/bin/gccopts.sh :
   Template Options file for building gcc MEX-files
2: <matlab>/bin/mexopts.sh :
   Template Options file for building MEX-files via the system ANSI compiler

Enter the number of the options file to use as your default options file:

Select the proper options file for your system by entering its number and pressing Return. If an options file doesn’t exist in your MATLAB directory, the system displays a message stating that the options file is being copied to your user-specific matlab directory. If an options file already exists in your MATLAB directory, the system prompts you to overwrite it.
Note The setup option creates a user-specific, \texttt{matlab} directory in your individual home directory and copies the appropriate options file to the directory. (If the directory already exists, a new one is not created.) This \texttt{matlab} directory is used for your individual options files only; each user can have his or her own default options files (other MATLAB products may place options files in this directory). Do not confuse these user-specific \texttt{matlab} directories with the system \texttt{matlab} directory, where MATLAB is installed.

Using the setup option resets your default compiler so that the new compiler is used every time you use the \texttt{mex} script.

Modifying the Options File. Another use of the setup option is if you want to change your options file settings. For example, if you want to make a change to the current linker settings, or you want to disable a particular set of warnings, you should use the setup option.

As the previous note says, setup copies the appropriate options file to your individual directory. To make your user-specific changes to the options file, you then edit your copy of the options file to correspond to your specific needs and save the modified file. This sets your default compiler’s options file to your specific version.

Temporarily Changing the Compiler. To temporarily change your C or C++ compiler, use the -f option, as in

\begin{verbatim}
  mex -f <file>
\end{verbatim}

The -f option tells the \texttt{mex} script to use the options file, \texttt{<file>}. If \texttt{<file>} is not in the current directory, then \texttt{<file>} must be the full pathname to the desired options file. Using the -f option tells the \texttt{mex} script to use the specified options file for the current execution of \texttt{mex} only; it does not reset the default compiler.

Creating MEX-Files
To create MEX-files on UNIX, first copy the source file(s) to a local directory, and then change directory (cd) to that local directory.
On UNIX, MEX-files are created with platform-specific extensions, as shown in Table 2-2, MEX-File Extensions for UNIX.

**Table 2-2: MEX-File Extensions for UNIX**

<table>
<thead>
<tr>
<th>Platform</th>
<th>MEX-File Extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dec/Compaq Alpha</td>
<td>mexaxp</td>
</tr>
<tr>
<td>HP 9000 PA-RISC</td>
<td>mexhp7</td>
</tr>
<tr>
<td>HP-UX</td>
<td>mexhpux</td>
</tr>
<tr>
<td>IBM RS/6000</td>
<td>mexrs6</td>
</tr>
<tr>
<td>Linux</td>
<td>mexglx</td>
</tr>
<tr>
<td>SGI</td>
<td>mexsg</td>
</tr>
<tr>
<td>Solaris</td>
<td>mexsol</td>
</tr>
</tbody>
</table>

The `<matlab>/extern/examples/mex` directory contains C source code for the example `yprime.c`. After you copy the source file (`yprime.c`) to a local directory and `cd` to that directory, enter at the MATLAB prompt

```
mex yprime.c
```

This should create the MEX-file called `yprime` with the appropriate extension corresponding to your UNIX platform. For example, if you create the MEX-file on Solaris, its name is `yprime.mexsol`.

You can now call `yprime` from the MATLAB prompt as if it were an M-function. For example:

```
yprime(1,1:4)
ans =
    2.0000    8.9685    4.0000   -1.0947
```

If you encounter problems generating the MEX-file or getting the correct results, refer to External Interfaces/API in the MATLAB documentation for additional information about MEX-files.
MATLAB Compiler Verification

Verifying from MATLAB

Once you have verified that you can generate MEX-files on your system, you are ready to verify that the MATLAB Compiler is correctly installed. Type the following at the MATLAB prompt.

```
mcc -x invhilb
```

After a short delay, this command should complete and display the MATLAB prompt. Next, at the MATLAB prompt, type

```
which invhilb
```

The `which` command should indicate that `invhilb` is now a MEX-file by listing the filename followed by the appropriate UNIX MEX-file extension. For example, if you run the Compiler on Solaris, the Compiler creates the file `invhilb.mexsol`. Finally, at the MATLAB prompt, type

```
invhilb(10)
```

Note that this tests only the Compiler’s ability to make MEX-files. If you want to create stand-alone applications, refer to Chapter 4, “Stand-Alone Applications” for additional details.

Verifying from UNIX Command Prompt

To verify that the Compiler can generate MEX-files from the UNIX command prompt, you follow a similar procedure as that used in the previous section.

**Note** Before you test to see if the Compiler can generate MEX-files from the UNIX command prompt, you may want to delete the MEX-file you created in the previous section, `invhilb.mexsol`, or whatever the extension is on your system. That way, you can be sure your newly generated MEX-file is the result of using the Compiler from the UNIX prompt.

Copy `invhilb.m` from the `<matlab>/toolbox/matlab/elmat` directory to a local directory and then type the following at the UNIX prompt:

```
mcc -x invhilb
```
Next, verify that invhilb is now a MEX-file by listing the invhilb files:

```
ls invhilb.*
```

You will see a list similar to this:

```
invhilb.c   invhilb.m   invhilb_mex.c
invhilb.h   invhilb.mexsol
```

These are the various files that the Compiler generates from the M-file. The Compiler-generated MEX-file appears in the list as the filename followed by the appropriate UNIX MEX-file extension. In this example, the Compiler was executed on Solaris, so the Compiler creates the file invhilb.mexsol. For more information on which files the Compiler creates for a compilation, see Chapter 5, “Controlling Code Generation.”

To test the newly created MEX-file, start MATLAB and, at the MATLAB prompt, type

```
invhilb(10)
```
Microsoft Windows on PCs

This section examines the system requirements, installation procedures, and configuration procedures for the MATLAB Compiler on PCs running Microsoft Windows.

System Requirements
You cannot install the MATLAB Compiler unless MATLAB 6.5 (Release 13) is already installed on the system. The MATLAB Compiler imposes no operating system or memory requirements beyond what is necessary to run MATLAB. The MATLAB Compiler consumes a small amount of disk space.

Table 2-3, Requirements for Creating PC Applications, shows the requirements for creating PC applications with the MATLAB Compiler.

<table>
<thead>
<tr>
<th>To create...</th>
<th>You need...</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEX-files</td>
<td>ANSI C compiler (see following note)</td>
</tr>

<td></td>
<td>MATLAB Compiler</td>
</tr>
<tr>
<td>Stand-alone C applications</td>
<td>ANSI C compiler (see following note)</td>
</tr>
<tr>
<td></td>
<td>MATLAB Compiler</td>
</tr>
<tr>
<td>Stand-alone C++ applications</td>
<td>C++ compiler</td>
</tr>
<tr>
<td></td>
<td>MATLAB Compiler</td>
</tr>
</tbody>
</table>

**Note** MATLAB includes an ANSI C compiler (Lcc) that is suitable for use with the MATLAB Compiler.

**Note** Although the MATLAB Compiler supports the creation of stand-alone C++ applications, it does not support the creation of C++ MEX-files.
Supported ANSI C and C++ PC Compilers
To create C MEX-files, stand-alone C/C++ applications, or dynamically linked libraries (DLLs) with the MATLAB Compiler, you must install and configure a supported C/C++ compiler. Use one of the following 32-bit C/C++ compilers that create 32-bit Windows dynamically linked libraries (DLLs) or Windows NT applications:

- Lcc C version 2.4 (included with MATLAB). This is a C only compiler; it does not work with C++.
- Watcom C/C++ versions 10.6 and 11.0
- Borland C++ versions 5.3, 5.4, 5.5, 5.6, and free 5.5. (You may see references to these compilers as Borland C++Builder versions 3.0, 4.0, 5.0, and 6.0.) For more information on the free Borland compiler and its associated command line tools, see http://community.borland.com.
- Microsoft Visual C/C++ (MSVC) versions 5.0, 6.0, and 7.0.

**Note** For a list of all the compilers supported by MATLAB, see the MathWorks Technical Support Department’s Technical Notes at

Applications generated by the MATLAB Compiler are 32-bit applications and only run on any MATLAB-supported Microsoft Windows systems. For a complete list of supported Windows platforms, see

Known Compiler Limitations. There are several known restrictions regarding the use of supported compilers:

- Some compilers, e.g., Watcom, do not handle denormalized floating-point values correctly. Denormalized floating-point numbers are numbers that are greater than 0 and less than the value of `DBL_MIN` in your compiler’s `float.h` file.

- The MATLAB Compiler sometimes will generate goto statements for complicated if conditions. The Borland C++ Compiler prohibits the goto statement within a try catch block. This error can occur if you use the `-A debugline:on` option, because its implementation uses try catch. To work around this limitation, simplify the if conditions.

- There is a limitation with the Borland C++ Compiler. In your M-code, if you use a constant number that includes a leading zero and contains the digit ‘8’ or ‘9’ before the decimal point, the Borland compiler will display the error message

  Error <file>.c <line>: Illegal octal digit in function <functionname>

  For example, the Borland compiler considers 009.0 an illegal octal integer as opposed to a legal floating-point constant, which is how it is defined in the ANSI C standard.

  As an aside, if all the digits are in the legal range for octal numbers (0-7), then the compiler will incorrectly treat the number as a floating-point value. So, if you have code such as

  \[ x = [007 \ 06 \ 10]; \]

  and want to use the Borland compiler, you should edit the M-code to remove the leading zeros and write it as

  \[ x = [7 \ 6 \ 10]; \]
Compiler Options Files
The MathWorks provides options files for every supported C or C++ compiler. These files contain the necessary flags and settings for the compiler. This table shows the preconfigured PC options files that are included with MATLAB.

<table>
<thead>
<tr>
<th>Compiler</th>
<th>Options File</th>

<td>bcc56opts.bat</td>
</tr>
</tbody>
</table>

Locating Options Files
To locate your options file, the mex script searches the following:

- The current directory
- The user profile directory (see the following section, “The User Profile Directory Under Windows,” for more information about this directory)

mex uses the first occurrence of the options file it finds. If no options file is found, mex searches your machine for a supported C compiler and uses the factory default options file for that compiler. If multiple compilers are found, you are prompted to select one.

The User Profile Directory Under Windows. The Windows user profile directory is a directory that contains user-specific information such as desktop appearance, recently used files, and Start menu items. The mex and mbuild utilities store their respective options files, mexopts.bat and compopts.bat, which are
created during the setup process, in a subdirectory of your user profile directory, named Application Data\MathWorks\MATLAB\R13. Under Windows with user profiles enabled, your user profile directory is %windir%\Profiles\username. Under Windows with user profiles disabled, your user profile directory is %windir%. You can determine whether or not user profiles are enabled by using the **Passwords** control panel.

**Installation**

**MATLAB Compiler**

To install the MATLAB Compiler on a PC, follow the instructions in the *Installation Guide for Windows*. If you have a license to install the MATLAB Compiler, it will appear as one of the installation choices that you can select as you proceed through the installation process.

If the Compiler does not appear in your list of choices, contact The MathWorks to obtain an updated License File (license.dat) for multiuser network installations, or an updated Personal License Password (PLP) for single-user, standard installations:

- Via the Web at www.mathworks.com. On the MathWorks home page, click on Support, then click on the Access Login, and follow the instructions.
- Via e-mail at service@mathworks.com

**ANSI C or C++ Compiler**

To install your ANSI C or C++ compiler, follow the vendor’s instructions that accompany your compiler. Be sure to test the C/C++ compiler to make sure it is installed and configured properly. The following section, “Things to Be Aware of,” contains some Windows-specific details regarding the installation and configuration of your C/C++ compiler.
### Things to Be Aware of

This table provides information regarding the installation and configuration of a C/C++ compiler on your system.

mex Verification

Choosing a Compiler

Systems with Exactly One C/C++ Compiler. If you have properly installed the MATLAB Compiler and your supported C or C++ compiler, you can now create C MEX-files. On systems where there is exactly one C or C++ compiler available to you, the mex utility automatically configures itself for the appropriate compiler. So, for many users, to create a C MEX-file, you can simply enter

```
mex filename.c
```

This simple method of creating MEX-files works for the majority of users. It uses your installed C or C++ compiler as your default compiler for creating your MEX-files.

If you are a user who does not need to change compilers, or you do not need to modify your compiler options files, you can skip ahead in this section to “Creating MEX-Files” on page 2-22.

Note On Windows 98 systems, if you get the error, out of environment space, see “Out of Environment Space Running mex or mbuild” on page 2-25 for more information.

Systems with More than One C/C++ Compiler. On systems where there is more than one C or C++ compiler, the mex utility lets you select which of the compilers you want to use. Once you choose your C or C++ compiler, that compiler becomes your default compiler and you no longer have to select one when you compile MEX-files.

For example, if your system has both the Borland and Watcom compilers, when you enter for the first time

```
mex filename.c
```

you are asked to select which compiler to use.

```
mex has detected the following compilers on your machine:
```
[1]: Borland compiler in T:\Borland\BC.500
[2]: WATCOM compiler in T:\watcom\c.106
[0]: None

Please select a compiler. This compiler will become the default:

Select the desired compiler by entering its number and pressing Return. You are then asked to verify the information.

Changing Compilers

Changing the Default Compiler. To change your default C or C++ compiler, you select a different options file. You can do this at any time by using the mex -setup option.

This example shows the process of changing your default compiler to the Microsoft Visual C/C++ Version 6.0 compiler.

mex -setup

Please choose your compiler for building external interface (MEX) files.

Would you like mex to locate installed compilers [y]/n? n

Select a compiler:
[1] Borland C++Builder version 6.0
[2] Borland C++Builder version 5.0
[3] Borland C++Builder version 4.0
[5] Borland C/C++ version 5.02
[6] Borland C/C++ version 5.0
[7] Borland C/C++ (free command line tools) version 5.5
[8] Compaq Visual Fortran version 6.6
[12] Lcc C version 2.4
Microsoft Visual C/C++ version 5.0
WATCOM C/C++ version 11
WATCOM C/C++ version 10.6
None

Compiler: 14

Your machine has a Microsoft Visual C/C++ compiler located at
D:\Applications\Microsoft Visual Studio. Do you want to use this
compiler [y]/n? y

Please verify your choices:

Compiler: Microsoft Visual C/C++ 6.0
Location: D:\Applications\Microsoft Visual Studio

Are these correct?([y]/n): y

The default options file:
"C:\WINNT\Profiles\username
\Application Data\MathWorks\MATLAB\R13\mexopts.bat" is being
updated...

Installing the MATLAB Visual Studio add-in ...

Updated ...

If the specified compiler cannot be located, you are given the message:

The default location for compiler-name is directory-name,
but that directory does not exist on this machine.
Use directory-name anyway [y]/n?

Using the setup option sets your default compiler so that the new compiler is
used everytime you use the mex script.

Modifying the Options File. Another use of the setup option is if you want to
change your options file settings. For example, if you want to make a change to
the current linker settings, or you want to disable a particular set of warnings,
you should use the setup option.
The setup option copies the appropriate options file to your user profile directory. To make your user-specific changes to the options file, you edit your copy of the options file in your user profile directory to correspond to your specific needs and save the modified file. After completing this process, the \texttt{mex} script will use the new options file everytime with your modified settings.

**Temporarily Changing the Compiler.** To temporarily change your C or C++ compiler, use the \texttt{-f} option, as in

\begin{verbatim}
mex -f <file>
\end{verbatim}

The \texttt{-f} option tells the \texttt{mex} script to use the options file, \texttt{<file>}. If \texttt{<file>} is not in the current directory, then \texttt{<file>} must be the full pathname to the desired options file. Using the \texttt{-f} option tells the \texttt{mex} script to use the specified options file for the current execution of \texttt{mex} only; it does not reset the default compiler.

**Creating MEX-Files**

The \texttt{<matlab>\extern\examples\mex} directory contains C source code for the example \texttt{yprime.c}. To verify that your system can create MEX-files, enter at the MATLAB prompt

\begin{verbatim}
cd([matlabroot '\extern\examples\mex'])
mex yprime.c
\end{verbatim}

This should create the \texttt{yprime.dll} MEX-file. MEX-files created on Windows always have the extension \texttt{dll}.

You can now call \texttt{yprime} as if it were an M-function. For example,

\begin{verbatim}
yprime(1,1:4)
\end{verbatim}

\begin{verbatim}
an =
    2.0000 8.9685 4.0000 -1.0947
\end{verbatim}

If you encounter problems generating the MEX-file or getting the correct results, refer to “External Interfaces/API” in the MATLAB documentation for additional information about MEX-files.

**MATLAB Add-In for Visual Studio**

The MathWorks provides a MATLAB add-in for the Visual Studio development system that lets you work easily within the Microsoft Visual C/C++ (MSVC) environment to create and debug MEX-files. The MATLAB add-in for Visual Studio is included with MATLAB and is automatically installed when you run
mex -setup and select Microsoft Visual C/C++ version 5 or 6. For more information about the add-in, see “Using an Integrated Development Environment” on page 4-23.

**Note** The MATLAB add-in for Visual Studio does not currently work with Microsoft Visual C/C++, Version 7.0.

**MATLAB Compiler Verification**

**Verifying from MATLAB**

Once you have verified that you can generate MEX-files on your system, you are ready to verify that the MATLAB Compiler is correctly installed. Type the following at the MATLAB prompt.

```
mcc -x invhilb
```

After a short delay, this command should complete and display the MATLAB prompt. Next, at the MATLAB prompt, type

```
which invhilb
```

The `which` command should indicate that `invhilb` is now a MEX-file; it should have created the file `invhilb.dll`. Finally, at the MATLAB prompt, type

```
invhilb(10)
```

Note that this tests only the Compiler’s ability to make MEX-files. If you want to create stand-alone applications or DLLs, refer to Chapter 4, “Stand-Alone Applications.”

**Verifying from DOS Command Prompt**

To verify that the Compiler can generate C MEX-files from the DOS command prompt, you follow a similar procedure as that used in the previous section.
Note  Before you test to see if the Compiler can generate MEX-files from the DOS command prompt, you may want to delete the MEX-file you created in the previous section, invhilb.dll. That way, you can be sure your newly generated MEX-file is the result of using the Compiler from the DOS prompt. To delete this file, you must clear the MEX-file or quit MATLAB; otherwise the deletion will fail.

Copy invhilb.m from the <matlab>\toolbox\matlab\elmat directory to a local directory and then type the following at the DOS prompt.

    mcc -x invhilb

Next, verify that invhilb is now a MEX-file by listing the invhilb files:

    dir invhilb*

You will see a list containing

    invhilb.c
    invhilb.dll
    invhilb.h
    invhilb.m
    invhilb_mex.c

These are the files that the Compiler generates from the M-file, in addition to the original M-file, invhilb.m. The Compiler-generated MEX-file appears in the list as the filename followed by the extension, dll. In this example, the Compiler creates the file invhilb.dll. For more information on which files the Compiler creates for a compilation, see Chapter 5, “Controlling Code Generation.”

To test the newly created MEX-file, you would start MATLAB and, at the MATLAB prompt, you could type

    invhilb(10)
Troubleshooting

This section identifies some of the more common problems that can occur when installing and configuring the MATLAB Compiler.

**mex Troubleshooting**

**Out of Environment Space Running mex or mbuild.** On Windows 98 systems, the `mex` and `mbuild` scripts require more than the default amount of environment space. If you get the error, `out of environment space`, add this line to your `config.sys` file.

```
shell=c:\command.com /e:32768 /p
```

On Windows Me systems, if you encounter this problem and are using the MATLAB add-in for Visual Studio, follow the procedure in “Configuring on Windows 98 and Windows Me Systems” on page 4-25.

**Non-ANSI C Compiler on UNIX.** A common configuration problem in creating C MEX-files on UNIX involves using a non-ANSI C compiler. You must use an ANSI C compiler.

**DLLs Not on Path on Windows.** MATLAB will fail to load MEX-files if it cannot find all DLLs referenced by the MEX-file; the DLLs must be on the DOS path or in the same directory as the MEX-file. This is also true for third-party DLLs.

**Segmentation Violation or Bus Error.** If your MEX-file causes a segmentation violation or bus error, there is most likely a problem with the MATLAB Compiler. Contact Technical Support at The MathWorks at support@mathworks.com.

**Generates Wrong Answers.** If your program generates the wrong answer(s), there are several possible causes. There could be an error in the computational logic or there may be a defect in the MATLAB Compiler. Run your original M-file with a set of sample data and record the results. Then run the associated MEX-file with the sample data and compare the results with those from the original M-file. If the results are the same, there may be a logic problem in your original M-file. If the results differ, there may be a defect in the MATLAB Compiler. In this case, send the pertinent information via e-mail to support@mathworks.com.
mex Works from Shell But Not from MATLAB (UNIX). If the command

```
mex -x yprime.c
```

works from the UNIX shell prompt but does not work from the MATLAB prompt, you may have a problem with your .cshrc file. When MATLAB launches a new C shell to perform compilations, it executes the .cshrc script. If this script causes unexpected changes to the PATH, an error may occur. You can test whether this is true by performing a

```
set SHELL=/bin/sh
```
prior to launching MATLAB. If this works correctly, then you should check your .cshrc file for problems setting the PATH.

Cannot Locate Your Compiler (PC). If mex has difficulty locating your installed compilers, it is useful to know how it goes about finding compilers. mex automatically detects your installed compilers by first searching for locations specified in the following environment variables:

- `BORLAND` for Borland C++ Compiler, Version 5.3
- `WATCOM` for the Watcom C/C++ Compiler
- `MSVCDIR` for Microsoft Visual C/C++, Version 5.0, 6.0, or 7.0

Next, mex searches the Windows registry for compiler entries. Note that Watcom does not add an entry to the registry. Digital Fortran does not use an environment variable; mex only looks for it in the registry.

Internal Error When Using mex -setup (PC). Some antivirus software packages such as Cheyenne AntiVirus and Dr. Solomon may conflict with the `mex -setup` process. If you get an error message during mex -setup of the following form

```
mex.bat: internal error in sub get_compiler_info(): don't recognize <string>
```

then you need to disable your antivirus software temporarily and rerun mex -setup. After you have successfully run the setup option, you can reenable your antivirus software.

Verification of mex Fails. If none of the previous solutions addresses your difficulty with mex, contact Technical Support at The MathWorks at support@mathworks.com.
Troubleshooting the Compiler

One problem that might occur when you try to use the Compiler involves licensing.

Licensing Problem. If you do not have a valid license for the MATLAB Compiler, you will get an error message similar to the following when you try to access the Compiler.

   Error: Could not check out a Compiler License:
   No such feature exists.

If you have a licensing problem, contact The MathWorks. A list of contacts at The MathWorks is provided at the beginning of this manual.

MATLAB Compiler Does Not Generate MEX-File. If you experience other problems with the MATLAB Compiler, contact Technical Support at The MathWorks at support@mathworks.com.
Installation and Configuration
Working with MEX-Files

This chapter gets you started compiling M-files with the MATLAB Compiler.

A Simple Example — The Sierpinski Gasket (p. 3-2)  
Creating a MEX-file from an M-file

Compiler Options and Macros (p. 3-6)  
Overview of options and macros

Generating Simulink S-Functions (p. 3-7)  
Generating Simulink C MEX S-functions

Converting Script M-Files to Function M-Files (p. 3-10)  
Converting scripts to functions
A Simple Example — The Sierpinski Gasket

Consider an M-file function called gasket.m:

```matlab
function theImage = gasket(numPoints)
%GASKET An image of a Sierpinski Gasket.
%   IM = GASKET(NUMPOINTS)
%
% Example:
%   x = gasket(50000);
%   imagesc(x);colormap([1 1 1;0 0 0]);
%   axis equal tight
%
% Copyright (c) 1984-98 by The MathWorks, Inc
% $Revision: 1.1 $  $Date: 1998/09/11 20:05:06 $

theImage = zeros(1000,1000);

corners = [866 1;1 500;866 1000];
startPoint = [866 1];
theRand = rand(numPoints,1);
theRand = ceil(theRand*3);

for i=1:numPoints
    startPoint = floor((corners(theRand(i),:)+startPoint)/2);
    theImage(startPoint(1),startPoint(2)) = 1;
end
```

How the Function Works

This function determines the coordinates of a Sierpinski Gasket using an Iterated Function System algorithm. The function starts with three points that define a triangle, and starting at one of these points, chooses one of the remaining points at random. A dot is placed at the midpoint of these two points. From the new point, a dot is placed at the midpoint between the new point and a point randomly selected from the original points. This process continues and eventually leads to an approximation of a curve.
The curve can be graphed in many ways. Sierpinski’s method is

- Start with a triangle and from it remove a triangle that is one-half the height of the original and inverted. This leaves three triangles.
- From each of the remaining three triangles, remove a triangle that is one-fourth the height of these new triangles and inverted. This leaves nine triangles.
- The process continues and at infinity the surface area becomes zero and the length of the curve is infinite.

To achieve a reasonable approximation of the Sierpinski Gasket, set the number of points to 50,000. To invoke the M-file and compute the coordinates, you can use

```matlab
x = gasket(50000);
```

To display the figure, you can use

```matlab
imagesc(x); colormap([1 1 1;0 0 0]);
axis equal tight
```

### Compiling the M-File into a MEX-File

To create a MEX-file from this M-file, enter the `mcc` command at the MATLAB interpreter prompt.

```matlab
mcc -x gasket
```

This `mcc` command generates

- A file named `gasket.c` containing MEX-file C source code.
- A file named `gasket.h` containing the public information.
- A file named `gasket_mex.c` containing the MEX-function interface (MEX wrapper).
- A MEX-file named `gasket.mex`. (The actual filename extension of the executable MEX-file varies depending on your platform, e.g., on the PC the file is named `gasket.dll`.)

`mcc` automatically invokes `mex` to create `gasket.mex` from `gasket.c` and `gasket_mex.c`. The `mex` utility encapsulates the appropriate C compiler and linker options for your system.
This example uses the -x macro option to create the MEX-file. For more information on this Compiler option, see the mcc reference page. For more information on the files that the Compiler generates, see Chapter 5, “Controlling Code Generation.”

**Invoking the MEX-File**

Invoke the MEX-file version of gasket from the MATLAB interpreter the same way you invoke the M-file version.

```matlab
x = gasket(50000);
```

MATLAB runs the MEX-file version (gasket.mex, which is gasket.dll on the PC) rather than the M-file version (gasket.m). Given an M-file and a MEX-file with the same root name (gasket) in the same directory, the MEX-file takes precedence.

**Note** To verify that the MEX-file version ran, use the which command

```matlab
which gasket
D:\work\gasket.dll
```

To display the Sierpinski Gasket, use

```matlab
imagesc(x); colormap([1 1 1;0 0 0]);
axis equal tight
```
Figure 3-1, The Sierpinski Gasket for 50,000 Points, shows the results.

Figure 3-1: The Sierpinski Gasket for 50,000 Points
Compiler Options and Macros

The MATLAB Compiler uses a family of options, also called option flags, to control the functionality of the Compiler. The `mcc` reference page includes a complete description of the Compiler options. Throughout this book you will see how these options are used with the Compiler to perform various tasks.

One particular set of Compiler options, macros, are particularly useful for performing straightforward compilations.

Macro options provide a simplified approach to compilation. Instead of manually grouping several options together to perform a particular type of compilation, you can use one simple option to quickly accomplish basic compilation tasks.

**Note** Macro options are intended to simplify the more common compilation tasks. You can always use individual options to customize the compilation process to satisfy your particular needs.

For detailed information about the macros included with the MATLAB Compiler, as well as complete information on all the other available Compiler options, see the `mcc` reference page.
Generating Simulink S-Functions

You can use the MATLAB Compiler to generate Simulink C MEX S-functions. This allows you to speed up Simulink models that contain MATLAB M-code that is referenced from a MATLAB Fcn block.

**Note** Only the MATLAB Fcn block is supported.

For more information about Simulink in general, see the Simulink documentation. For more information about Simulink S-functions, see “Writing S-Functions” in the Simulink documentation.

**Simulink Specific Options**

By using Simulink specific options with the MATLAB Compiler, you can generate an S-function that is compatible with the S-Function block. The Simulink specific options are -S, -u, and -y. Using any of these options with the MATLAB Compiler causes it to generate code that is compatible with Simulink.

**Using the -S Option**

The simplest S-function that the MATLAB Compiler can generate is one with a dynamically sized number of inputs and outputs. That is, you can pass any number of inputs and outputs in or out of the S-function. Both the MATLAB Fcn block and the S-Function block are single-input, single-output blocks. Only one line can be connected to the input or output of these blocks. However, each line may be a vector signal, essentially giving these blocks multi-input, multi-output capability. To generate a C language S-function of this type from an M-file, use the -S option:

```
mcc -S mfilename
```

**Note** The MATLAB Compiler option that generates a C language S-function is a capital S (-S).
The result is an S-function described in the following files:

```plaintext
mfilename.c
mfilename.h
mfilename_simulink.c
mfilename.ext
```
(where ext is the MEX-file extension for your platform, e.g., dll for Windows)

**Using the -u and -y Options**

Using the -S option by itself will generate code suitable for most general applications. However, if you would like to exert more control over the number of valid inputs or outputs for your function, you should use the -u and/or -y options. These options specifically set the number of inputs (u) and the number of outputs (y) for your function. If either -u or -y is omitted, the respective input or output will be dynamically sized:

```
mcc -S -u 1 -y 2 mfilename
```

In the above line, the S-function will be generated with an input vector whose width is 1 and an output vector whose width is 2. If you were to connect the referencing S-Function block to signals that do not correspond to the correct number of inputs or outputs, Simulink will generate an error when the simulation starts.

---

**Note** The MATLAB Compiler -S option does not support the passing of parameters, which is normally available with Simulink S-functions.

---

**Specifying S-Function Characteristics**

**Sample Time**

Similar to the MATLAB Fcn block, the automatically generated S-function has an inherited sample time.
Data Type
The input and output vectors for the Simulink S-function must be double-precision vectors or scalars. You must ensure that the variables you use in the M-code for input and output are also double-precision values.

Note  Simulink S-functions that are generated via the -S option of the Compiler are not currently compatible with Real-Time Workshop®. They can, however, be used to rapidly prototype code in Simulink.
Converting Script M-Files to Function M-Files

MATLAB provides two ways to package sequences of MATLAB commands:

- Function M-files
- Script M-files

These two categories of M-files differ in two important respects:

- You can pass arguments to function M-files but not to script M-files.
- Variables used inside function M-files are local to that function; you cannot access these variables from the MATLAB interpreter's workspace unless they are passed back by the function. By contrast, variables used inside script M-files are shared with the caller's workspace; you can access these variables from the MATLAB interpreter command line.

The MATLAB Compiler cannot compile script M-files nor can it compile a function M-file that calls a script.

Converting a script into a function is usually fairly simple. To convert a script to a function, simply add a function header line:

```
function [m,t] = houdini(sz)
```

For example, consider the script M-file `houdini.m`:

```
m = magic(4); % Assign 4x4 matrix to m.
t = m .^ 3;   % Cube each element of m.
disp(t);     % Display the value of t.
```

Running this script M-file from a MATLAB session creates variables `m` and `t` in your MATLAB workspace.

The MATLAB Compiler cannot compile `houdini.m` because `houdini.m` is a script. Convert this script M-file into a function M-file by simply adding a function header line:

```
function [m,t] = houdini(sz)
    m = magic(sz); % Assign matrix to m.
    t = m .^ 3;   % Cube each element of m.
    disp(t);     % Display the value of t.
```

The MATLAB Compiler can now compile `houdini.m`. However, because this makes `houdini` a function, running `houdini.mex` no longer creates variable `m`
in the MATLAB workspace. If it is important to have \( m \) accessible from the MATLAB workspace, you can change the beginning of the function to

```matlab
function [m,t] = houdini
```
Stand-Alone Applications

This chapter explains how to use the MATLAB Compiler to code and build stand-alone applications. Stand-alone applications run without the help of the MATLAB interpreter. In fact, stand-alone applications run even if MATLAB is not installed on the system. However, stand-alone applications do require the run-time shared libraries, which are detailed in the corresponding sections.

Differences Between MEX-Files and Stand-Alone Applications

MEX-files and stand-alone applications differ in these respects:

- MEX-files run in the same process space as the MATLAB interpreter. When you invoke a MEX-file, the MATLAB interpreter dynamically links in the MEX-file.
- Stand-alone C or C++ applications run independently of MATLAB.

MEX-Files

It is now possible to call MEX-files from Compiler-generated stand-alone applications. The Compiler will compile MEX-files whenever they are specified on the command line or are located using the -h option to find helper functions. The MEX-files will then be loaded and called by the stand-alone code.

If an M-file and a MEX-file appear in the same directory and the M-file contains at least one function, the Compiler will compile the M-file instead of the MEX-file. If the MEX-file is desired instead, you must use the %#mex pragma. For more information on this pragma, see the %#mex reference page.

Note The Compiler-generated code cannot invoke Compiler-generated MEX-files. Specify the M-file(s) source instead and the Compiler will compile those into the stand-alone application.

Stand-Alone C Applications

To build stand-alone C applications as described in this chapter, MATLAB, the MATLAB Compiler, a C compiler, and the MATLAB C/C++ Math Library must be installed on your system.

The source code for a stand-alone C application consists either entirely of M-files or some combination of M-files, MEX-files, and C or C++ source code files.

The MATLAB Compiler translates input M-files into C source code suitable for your own stand-alone applications. After compiling this C source code, the resulting object file is linked with the object libraries.
For more information about distributing a C application, see “Distributing Stand-Alone Applications” on page 4-27.

**Note** If you attempt to compile M-files to produce stand-alone applications and you do not have the MATLAB C/C++ Math Library installed, the system will not be able to find the appropriate libraries and the linking will fail. Also, if you do not have the MATLAB C/C++ Graphics Library installed, the MATLAB Compiler will generate run-time errors if the graphics functions are called.

**Stand-Alone C++ Applications**

To build stand-alone C++ applications, MATLAB, the MATLAB Compiler, a C++ compiler, and the MATLAB C/C++ Math Library must be installed on your system.

The source code for a stand-alone C++ application consists either entirely of M-files or some combination of M-files, MEX-files, and C or C++ source code files.

The MATLAB Compiler, when invoked with the appropriate option flag (-p or -L Cpp), translates input M-files into C++ source code suitable for your own stand-alone applications. After compiling this C++ source code, the resulting object files are linked against the MATLAB C/C++ Math Library. For more information about distributing a C++ application, see “Distributing Stand-Alone Applications” on page 4-27.

**Note** On the PC, the MATLAB C++ Math Library is static because the different PC compiler vendors use different C++ name-mangling algorithms.
Building Stand-Alone C/C++ Applications

This section explains how to build stand-alone C and C++ applications on UNIX systems and PCs running Microsoft Windows.

This section begins with a summary of the steps involved in building stand-alone C/C++ applications, including the `mbuild` script, which helps automate the build process, and then describes platform-specific issues for both supported platforms.

**Note** This chapter assumes that you have installed and configured the MATLAB Compiler.

**Overview**

On both operating systems, the steps you use to build stand-alone C and C++ applications are

1. Verify that `mbuild` can create stand-alone applications.

2. Verify that the MATLAB Compiler can link object files with the proper libraries to form a stand-alone application.
Figure 4-1, Sequence for Creating Stand-Alone C/C++ Applications, shows the sequence on both platforms. The sections following the flowchart provide more specific details for the individual platforms.

Figure 4-1: Sequence for Creating Stand-Alone C/C++ Applications

Packaging Stand-Alone Applications
To distribute a stand-alone application, you must include the application's executable as well as the shared libraries with which the application was linked. The necessary shared libraries vary by platform. The individual UNIX and Windows sections that follow provide more information about packaging applications.
Getting Started

Introducing mbuild

The MathWorks utility, mbuild, lets you customize the configuration and build process. The mbuild script provides an easy way for you to specify an options file that lets you

- Set your compiler and linker settings
- Change compilers or compiler settings
- Switch between C and C++ development
- Build your application

The MATLAB Compiler (mcc) automatically invokes mbuild under certain conditions. In particular, mcc -m or mcc -p invokes mbuild to perform compilation and linking. See the mcc reference page for complete details on which Compiler options you should use in order to use the mbuild script.

If you do not want mcc to invoke mbuild automatically, you can use the -c option, for example, mcc -mc filename.

Compiler Options Files

Options files contain the required compiler and linker settings for your particular C or C++ compiler. The MathWorks provides options files for every supported C or C++ compiler. The options file for UNIX is mbuildopts.sh; Table 4-3, Compiler Options Files on the PC, contains the PC options files.

Much of the information on options files in this chapter is provided for those users who may need to modify an options file to suit their specific needs. Many users never have to be concerned with how the options files work.

Note If you are developing C++ applications, make sure your C++ compiler supports the templates features of the C++ language. If it does not, you may be unable to use the MATLAB C/C++ Math Library.
Building Stand-Alone Applications on UNIX

This section explains how to compile and link C or C++ source code into a stand-alone UNIX application. This section includes

- “Configuring for C or C++” on page 4-7
- “Preparing to Compile” on page 4-8
- “Verifying mbuild” on page 4-11
- “Verifying the MATLAB Compiler” on page 4-12
- “About the mbuild Script” on page 4-13
- “Packaging UNIX Applications” on page 4-13

Configuring for C or C++

The mbuild script deduces the type of files you are compiling by the file extension. If you include both C and C++ files, mbuild uses the C++ compiler and the MATLAB C++ Math Library. If mbuild cannot deduce from the file extensions whether to compile C or C++, mbuild invokes the C compiler. The MATLAB Compiler generates only .c and .cpp files. Table 4-1, UNIX File Extensions for mbuild, shows the supported file extensions.

<table>
<thead>
<tr>
<th>Language</th>
<th>Extension(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>.c</td>
</tr>
<tr>
<td>C++</td>
<td>.cpp .C .cxx .cc</td>
</tr>
</tbody>
</table>

Note You can override the language choice that is determined from the extension by using the -lang option of mbuild. For more information about this option, as well as all of the other mbuild options, see the mbuild reference page.
Locating Options Files

`mbuild` locates your options file by searching the following:

- The current directory
- `$HOME/.matlab/R13`
- `<matlab>/bin`

`mbuild` uses the first occurrence of the options file it finds. If no options file is found, `mbuild` displays an error message.

Preparing to Compile

**Note** Refer to “Supported ANSI C and C++ UNIX Compilers” on page 2-4 for information about supported compilers and important limitations.

Using the System Compiler

If the MATLAB Compiler and your supported C or C++ compiler are installed on your system, you are ready to create C or C++ stand-alone applications. To create a stand-alone C application, you can simply enter

```
mbuild filename.c
```

This simple method works for the majority of users. Assuming `filename.c` contains a `main` function, this example uses the system’s compiler as your default compiler for creating your stand-alone application. If you are a user who does not need to change C or C++ compilers, or you do not need to modify your compiler options files, you can skip ahead in this section to “Verifying `mbuild`” on page 4-11. If you need to know how to change the options file or select a different compiler, continue with this section.

Changing Compilers

**Changing the Default Compiler.** You need to use the `setup` option if you want to change any options or link against different libraries. At the UNIX prompt type

```
mbuild -setup
```
The setup option creates a user-specific options file for your ANSI C or C++ compiler. Executing `mbuild -setup` presents a list of options files currently included in the `bin` subdirectory of MATLAB:

```
mbuild -setup
```

Using the 'mbuild -setup' command selects an options file that is placed in `~/.matlab/R13` and used by default for 'mbuild'. An options file in the current working directory or specified on the command line overrides the default options file in `~/.matlab/R13`.

Options files control which compiler to use, the compiler and link command options, and the runtime libraries to link against.

To override the default options file, use the 'mbuild -f' command (see 'mbuild -help' for more information).

The options files available for mbuild are:

1: `/matlab/bin/mbuildopts.sh`:
   - Build and link with MATLAB C/C++ Math Library

Enter the number of the options file to use as your default options file:

If there is more than one options file, you can select the one you want by entering its number and pressing `Return`. If there is only one options file available, it is automatically copied to your MATLAB directory if you do not already have an `mbuild` options file. If you already have an `mbuild` options file, you are prompted to overwrite the existing one.

**Note** The options file is stored in the `.matlab/R13` subdirectory of your home directory. This allows each user to have a separate `mbuild` configuration.

Using the setup option sets your default compiler so that the new compiler is used everytime you use the `mbuild` script.

**Modifying the Options File.** Another use of the setup option is if you want to change your options file settings. For example, if you want to make a change to
the current linker settings, or you want to disable a particular set of warnings, you should use the setup option.

If you need to change the options that \texttt{mbuild} passes to your compiler or linker, you must first run

\begin{verbatim}
  mbuild -setup
\end{verbatim}

which copies a master options file to your local MATLAB directory, typically \texttt{/home/.matlab/R13/mbuildopts.sh}.

If you need to see which options \texttt{mbuild} passes to your compiler and linker, use the verbose option, \texttt{-v}, as in

\begin{verbatim}
  mbuild -v filename1 [filename2 ]
\end{verbatim}

to generate a list of all the current compiler settings. To change the options, use an editor to make changes to your options file, which is in your local \texttt{matlab} directory. Your local \texttt{matlab} directory is a user-specific, MATLAB directory in your individual home directory that is used specifically for your individual options files. You can also embed the settings obtained from the verbose option of \texttt{mbuild} into an integrated development environment (IDE) or makefile that you need to maintain outside of MATLAB. Often, however, it is easier to call \texttt{mbuild} from your makefile. See your system documentation for information on writing makefiles.

\begin{note}
Any changes made to the local options file will be overwritten if you execute \texttt{mbuild -setup}. To make the changes persist through repeated uses of \texttt{mbuild -setup}, you must edit the master file itself, \texttt{<matlab>/bin/mbuildopts.sh}.
\end{note}

**Temporarily Changing the Compiler.** To temporarily change your C or C++ compiler, use the \texttt{-f} option, as in

\begin{verbatim}
  mbuild -f <file>
\end{verbatim}

The \texttt{-f} option tells the \texttt{mbuild} script to use the options file, \texttt{<file>}. If \texttt{<file>} is not in the current directory, then \texttt{<file>} must be the full pathname to the desired options file. Using the \texttt{-f} option tells the \texttt{mbuild} script to use the specified options file for the current execution of \texttt{mbuild} only; it does not reset the default compiler.
Verifying mbuild

There is C source code for an example ex1.c included in the <matlab>/extern/examples/cmath directory, where <matlab> represents the top-level directory where MATLAB is installed on your system. To verify that mbuild is properly configured on your system to create stand-alone applications, copy ex1.c to your local directory and type cd to change to that directory. Then, at the MATLAB prompt, enter

    mbuild ex1.c

This creates the file called ex1. Stand-alone applications created on UNIX systems do not have any extensions.

Locating Shared Libraries

Before you can run your stand-alone application, you must tell the system where the API and C shared libraries reside. This table provides the necessary UNIX commands depending on your system’s architecture.

<table>
<thead>
<tr>
<th>Architecture</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>HP700/HP-UX</td>
<td>setenv SHLIB_PATH &lt;matlab&gt;/extern/lib/&lt;arch&gt;:$SHLIB_PATH</td>
</tr>
<tr>
<td>IBM RS/6000</td>
<td>setenv LIBPATH &lt;matlab&gt;/extern/lib/ibm_rs:$LIBPATH</td>
</tr>
<tr>
<td>All others</td>
<td>setenv LD_LIBRARY_PATH &lt;matlab&gt;/extern/lib/&lt;arch&gt;:$LD_LIBRARY_PATH</td>
</tr>
</tbody>
</table>

where:
<matlab> is the MATLAB root directory
<arch> is your architecture (i.e., alpha, hp700, hpux, lnx86, sgi, sg164, or sol2)

It is convenient to place this command in a startup script such as ~/.cshrc. Then the system will be able to locate these shared libraries automatically, and you will not have to reissue the command at the start of each login session.

Note On all UNIX platforms, the Compiler library is shipped as a shared object (.so) file or shared library (.sl). Any Compiler-generated, stand-alone application must be able to locate the C/C++ libraries along the library path environment variable (SHLIB_PATH, LIBPATH, or LD_LIBRARY_PATH) in order to
be found and loaded. Consequently, to share a Compiler-generated, stand-alone application with another user, you must provide all of the required shared libraries. For more information about the required shared libraries for UNIX, see “Packaging UNIX Applications” on page 4-13.

### Running Your Application

To launch your application, enter its name on the command line. For example:

```matlab
ex1
ans =

1     3     5
2     4     6

ans =

1.0000 + 7.0000i   4.0000 +10.0000i
2.0000 + 8.0000i   5.0000 +11.0000i
3.0000 + 9.0000i   6.0000 +12.0000i
```

### Verifying the MATLAB Compiler

There is MATLAB code for an example, `hello.m`, included in the `<matlab>/extern/examples/compiler` directory. To verify that the MATLAB Compiler can generate stand-alone applications on your system, type the following at the MATLAB prompt:

```
mcc -m hello.m
```

This command should complete without errors. To run the stand-alone application, `hello`, invoke it as you would any other UNIX application, typically by typing its name at the UNIX prompt. The application should run and display the message

```
Hello, World
```

When you execute the `mcc` command to link files and libraries, `mcc` actually calls the `mbuild` script to perform the functions.
About the `mbuild` Script

The `mbuild` script supports various options that allow you to customize the building and linking of your code. Many users do not need to know any additional details of the `mbuild` script; they use it in its simplest form. For complete information about the `mbuild` script and its options, see the `mbuild` reference page.

Packaging UNIX Applications

To distribute a stand-alone UNIX application, you must create a package containing these files:

- Your application executable.
- The contents, if any, of a directory named `bin`, created by `mbuild` in the same directory as your application executable. Note: `mbuild` does not create a `bin` directory for every stand-alone application.
- Any custom MEX-files your application uses.
- All the MATLAB run-time libraries.

For specific information about packaging these files, see “Distributing Stand-Alone Applications” on page 4-27.

Distribution Caveats

**Locating Shared Libraries.** Remember to locate the shared libraries along the `LD_LIBRARY_PATH` (or `SHLIB_PATH` on HP) environment variable so that they can be found and loaded.

**Graphics Support on IBM_RS.** There is no support for the MATLAB C/C++ Graphics Library on the IBM_RS platform.

**C++ and Fortran Support on Digital UNIX.** MATLAB users require access to both the C++ and Fortran run-time shared libraries. These are usually provided as part of the operating system installation. For Digital UNIX, however, the C++ shared libraries are part of the base installation package, but the Fortran shared libraries are on a separate disk called the “Associated Products CD.” MATLAB users running under Digital UNIX should install both the C++ and Fortran run-time shared libraries.
**Note** If you distribute an application created with the math libraries on Digital UNIX, your users must have both the C++ and Fortran run-time shared libraries installed on their systems.
Building Stand-Alone Applications on PCs

This section explains how to compile and link the C/C++ code generated from the MATLAB Compiler into a stand-alone Windows application. This section includes

- “Configuring for C or C++” on page 4-15
- “Preparing to Compile” on page 4-16
- “Verifying mbuild” on page 4-22
- “Verifying the MATLAB Compiler” on page 4-23
- “About the mbuild Script” on page 4-23
- “Using an Integrated Development Environment” on page 4-23
- “Distributing Stand-Alone Applications” on page 4-27

Configuring for C or C++

mbuild determines whether to compile in C or C++ by examining the type of files you are compiling. Table 4-2, Windows File Extensions for mbuild, shows the file extensions that mbuild interprets as indicating C or C++ files.

<table>
<thead>
<tr>
<th>Language</th>
<th>Extension(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>.c</td>
</tr>
<tr>
<td>C++</td>
<td>.cpp, .cxx, .cc</td>
</tr>
</tbody>
</table>

- If you include both C and C++ files, mbuild uses the C++ compiler and the MATLAB C++ Math Library.
- If mbuild cannot deduce from the file extensions whether to compile in C or C++, mbuild invokes the C compiler.
Note You can override the language choice that is determined from the extension by using the -lang option of `mbuild`. For more information about this option, as well as all of the other `mbuild` options, see the `mbuild` reference page.

Locating Options Files
To locate your options file, the `mbuild` script searches the following:

- The current directory
- The user profile directory (For more information about this directory, see “The User Profile Directory Under Windows” on page 2-16.)

`mbuild` uses the first occurrence of the options file it finds. If no options file is found, `mbuild` searches your machine for a supported C compiler and uses the factory default options file for that compiler. If multiple compilers are found, you are prompted to select one.

Preparing to Compile

Compiler Restrictions
Some of the supported PC compilers have restrictions regarding their use with the MATLAB Compiler. Refer to “Supported ANSI C and C++ PC Compilers” on page 2-14 for important limitation information on the supported compilers.

Other restrictions include

- Watcom 10.6 and 11.0 are not supported for building stand-alone applications.
- The Lcc C compiler does not support C++.
- The only compilers that support the building of COM objects are Borland C++Builder (versions 3.0, 4.0, 5.0, and 6.0) and Microsoft Visual C/C++ (versions 5.0, 6.0, and 7.0).
Choosing a Compiler

Systems with Exactly One C/C++ Compiler. If the MATLAB Compiler and your supported C or C++ compiler are installed on your system, you are ready to create C or C++ stand-alone applications. On systems where there is exactly one C or C++ compiler available to you, the mbuild utility automatically configures itself for the appropriate compiler. So, for many users, to create a C or C++ stand-alone applications, you can simply enter

```bash
mbuild filename.c
```

This simple method works for the majority of users. Assuming `filename.c` contains a `main` function, this example uses your installed C or C++ compiler as your default compiler for creating your stand-alone application. If you are a user who does not need to change compilers, or you do not need to modify your compiler options files, you can skip ahead in this section to “Verifying mbuild” on page 4-22. If you need to know how to change the options file or select a different compiler, continue with this section.

Note On Windows 98 systems, if you get the error, out of environment space, see “Out of Environment Space Running mex or mbuild” on page 4-33 for more information.

Systems with More than One C/C++ Compiler. On systems where there is more than one C or C++ compiler, the mbuild utility lets you select which of the compilers you want to use. Once you choose your C or C++ compiler, that compiler becomes your default compiler and you no longer have to select one when you compile your stand-alone applications.

For example, if your system has both the Lcc and Microsoft Visual C/C++ compilers, when you enter for the first time

```bash
mbuild filename.c
```

you are asked to select which compiler to use:

```bash
Please choose your compiler for building stand-alone MATLAB applications:
```

```bash
Select a compiler:
```
Select the desired compiler by entering its number and pressing **Return**. You are then asked to verify your information.

**Changing Compilers**

**Changing the Default Compiler.** To change your default C or C++ compiler, you select a different options file. You can do this at anytime by using the `setup` command.

This example shows the process of changing your default compiler to the Microsoft Visual C/C++ Version 6.0 compiler:

```
mbuild -setup
```

Please choose your compiler for building stand-alone MATLAB applications.

Would you like mbuild to locate installed compilers [y]/n? n

Select a compiler:

[1] Borland C++Builder version 6.0
[2] Borland C++Builder version 5.0
[3] Borland C++Builder version 4.0
[5] Borland C/C++ version 5.02
[6] Borland C/C++ version 5.0
[7] Borland C/C++ (free command line tools) version 5.5
[8] Lcc C version 2.4

[0] None
Compiler: 10

Your machine has a Microsoft Visual C/C++ compiler located at D:\Applications\Microsoft Visual Studio. Do you want to use this compiler [y]/n? y

Please verify your choices:

Compiler: Microsoft Visual C/C++ 6.0
Location: D:\Applications\Microsoft Visual Studio

Are these correct?([y]/n): y

The default options file:
"C:\WINNT\Profiles\username\Application Data\MathWorks\MATLAB\R13\compopts.bat"
is being updated...

Installing the MATLAB Visual Studio add-in ...

Updated ...

If the specified compiler cannot be located, you are given the message

The default location for <compiler-name> is <directory-name>, but that directory does not exist on this machine.

Use <directory-name> anyway [y]/n?

Using the setup option sets your default compiler so that the new compiler is used everytime you use the mbuild script.

Modifying the Options File. Another use of the setup option is if you want to change your options file settings. For example, if you want to make a change to the current linker settings, or you want to disable a particular set of warnings, you should use the setup option.

The setup option copies the appropriate options file to your user profile directory. To make your user-specific changes to the options file, you edit your copy of the options file in your user profile directory to correspond to your
specific needs and save the modified file. This sets your default compiler’s options file to your specific version. Table 4-3, Compiler Options Files on the PC, lists the names of the PC options files included in this release of MATLAB. If you need to see which options `mbuild` passes to your compiler and linker, use the verbose option, `-v`, as in

```
mbuild -v filename1 [filename2 ...]
```

to generate a list of all the current compiler settings used by `mbuild`. To change the options, use an editor to make changes to your options file that corresponds to your compiler. You can also embed the settings obtained from the verbose option into an integrated development environment (IDE) or makefile that you need to maintain outside of MATLAB. Often, however, it is easier to call `mbuild` from your makefile. See your system documentation for information on writing makefiles.

**Note** Any changes that you make to the local options file `compopts.bat` will be overwritten the next time you run `mbuild -setup`. If you want to make your edits persist through repeated uses of `mbuild -setup`, you must edit the master file itself. The master options files are also located in `<matlab>\bin`.

### Table 4-3: Compiler Options Files on the PC

<table>
<thead>
<tr>
<th>Compiler</th>
<th>Master Options File</th>
</tr>
</thead>
<tbody>
<tr>
<td>Borland C++Builder, Version 3.0</td>
<td>bcc53compp.bat</td>
</tr>
<tr>
<td>Borland C++Builder, Version 4.0</td>
<td>bcc54compp.bat</td>
</tr>
<tr>
<td>Borland C++Builder, Version 5.0</td>

<tr>
<td>Microsoft Visual C/C++, Version 5.0</td>
<td>msvc50compp.bat</td>
</tr>
</tbody>
</table>
Combining Customized C and C++ Options Files. The options files for \texttt{mbuild} have changed as of MATLAB 5.3 (Release 11) so that the same options file can be used to create both C and C++ stand-alone applications. If you have modified your own separate options files to create C and C++ applications, you can combine them into one options file.

To combine your existing options files into one universal C and C++ options file:

1. Copy from the C++ options file to the C options file all lines that set the variables \texttt{COMPFLAGS}, \texttt{OPTIMFLAGS}, \texttt{DEBUGFLAGS}, and \texttt{LINKFLAGS}.

2. In the C options file, within just those copied lines from step 1, replace all occurrences of:
   - \texttt{COMPFLAGS} with \texttt{CPPCOMPFLAGS}
   - \texttt{OPTIMFLAGS} with \texttt{CPPOPTIMFLAGS}
   - \texttt{DEBUGFLAGS} with \texttt{CPPDEBUGFLAGS}
   - \texttt{LINKFLAGS} with \texttt{CPPLINKFLAGS}.

This process modifies your C options file to be a universal C/C++ options file.

Temporarily Changing the Compiler. To temporarily change your C or C++ compiler, use the \texttt{-f} option, as in

\begin{verbatim}
mbuild -f <file>
\end{verbatim}

The \texttt{-f} option tells the \texttt{mbuild} script to use the options file, \texttt{<file>}. If \texttt{<file>} is not in the current directory, then \texttt{<file>} must be the full pathname to the desired options file. Using the \texttt{-f} option tells the \texttt{mbuild} script to use the specified options file for the current execution of \texttt{mbuild} only; it does not reset the default compiler.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
Compiler & Master Options File \\
\hline
Microsoft Visual C/C++, Version 6.0 & msvc60compp.bat \\
Microsoft Visual C/C++, Version 7.0 & msvc70compp.bat \\
\hline
\end{tabular}
\caption{Compiler Options Files on the PC (Continued)}
\end{table}
Verifying mbuild

There is C source code for an example, ex1.c, included in the
<matlab>\extern\examples\cmath directory, where <matlab> represents the
top-level directory where MATLAB is installed on your system. To verify that
mbuild is properly configured on your system to create stand-alone
applications, enter at the MATLAB prompt

mbuild ex1.c

This creates the file called ex1.exe. Stand-alone applications created on
Windows 98/2000/Me or Windows NT always have the extension exe. The
created application is a 32-bit MS-DOS console application.

Shared Libraries

All the libraries (WIN32 Dynamic Link Libraries, or DLLs) for MATLAB, the
MATLAB Compiler, and the MATLAB Math Library are in the directory

<matlab>\bin\win32

The .DEF files for the Microsoft and Borland compilers are in the
<matlab>\extern\include directory. All of the relevant libraries for building
stand-alone applications are WIN32 Dynamic Link Libraries. Before running
a stand-alone application, you must ensure that the directory containing the
DLLs is on your path. The directory must be on your operating system $PATH
environment variable. On Windows NT, use the Control Panel to set the value.

Running Your Application

You can now run your stand-alone application by launching it from the DOS
command line. For example:

    ex1

ans =

    1  3  5
    2  4  6

ans =
Verifying the MATLAB Compiler

There is MATLAB code for an example, hello.m, included in the \extern\examples\compiler directory. To verify that the MATLAB Compiler can generate stand-alone applications on your system, type the following at the MATLAB prompt.

\texttt{mcc -m hello.m}

This command should complete without errors. To run the stand-alone application, hello, invoke it as you would any other Windows console application, by typing its name on the MS-DOS command line. The application should run and display the message \texttt{Hello, World}.

When you execute the \texttt{mcc} command to link files and libraries, \texttt{mcc} actually calls the \texttt{mbuild} script to perform the functions.

About the \texttt{mbuild} Script

The \texttt{mbuild} script supports various options that allow you to customize the building and linking of your code. Many users do not need to know any additional details of the \texttt{mbuild} script; they use it in its simplest form. For complete information about the \texttt{mbuild} script and its options, see the \texttt{mbuild} reference page.

Using an Integrated Development Environment

The MathWorks provides a MATLAB add-in for the Visual Studio development system that lets you work easily within the Microsoft Visual C/C++ (MSVC) integrated development environment (IDE). The MATLAB add-in for Visual Studio greatly simplifies using M-files in the MSVC environment. The add-in automates the integration of M-files into Visual C++ projects. It is fully integrated with the MSVC environment.

The add-in for Visual Studio is automatically installed on your system when you run either \texttt{mbuild \textendash setup} or \texttt{mex \textendash setup} and select Microsoft Visual C/C++ version 5 or 6. However, there are several steps you must follow in order to use the add-in:

1. To build MEX-files with the add-in for Visual Studio, run the following command at the MATLAB command prompt:
   \begin{verbatim}
   mex \textendash setup
   \end{verbatim}
   Follow the menus and choose either Microsoft Visual C/C++ 5.0 or 6.0. This configures \texttt{mex} to use the selected Microsoft compiler and also installs the necessary add-in files in your Microsoft Visual C/C++ directories.

2. To build stand-alone applications with the MATLAB add-in for Visual Studio (requires the MATLAB Compiler and the MATLAB C/C++ Math Libraries), run the following command at the MATLAB command prompt:
   \begin{verbatim}
   mbuild \textendash setup
   \end{verbatim}
   Follow the menus and choose either Microsoft Visual C/C++ 5.0 or 6.0. This configures \texttt{mbuild} to use the selected Microsoft compiler and also installs the necessary add-in files into your Microsoft Visual C/C++ directories. (It is not a problem if these overlap with the files installed by the \texttt{mex \textendash setup} command.)

3. For either \texttt{mex} or stand-alone support, you should also run the following commands at the MATLAB prompt:
   \begin{verbatim}
   cd(prefdir); mccsavepath;
   \end{verbatim}
   These commands save your current MATLAB path to a file named \texttt{mccpath} in your user preferences directory. (Type \texttt{prefdir} to see the name of your user preferences directory.)

   This step is necessary because the MATLAB add-in for Visual Studio runs outside of the MATLAB environment, so it would have no way to determine
your MATLAB path. If you add directories to your MATLAB path and want them to be visible to the MATLAB add-in, rerun the cd and mccsavepath commands shown in this step and replace prefdir with the desired pathname.

4 To configure the MATLAB add-in for Visual Studio to work with Microsoft Visual C/C++:
   a Select Tools -> Customize from the MSVC menu.
   b Click on the Add-ins and Macro Files tab.
   c Select MATLAB for Visual Studio on the Add-ins and Macro Files list and click Close. The floating MATLAB add-in for Visual Studio toolbar appears. Selecting MATLAB for Visual Studio directs MSVC to automatically load the add-in when you start MSVC again.

Configuring on Windows 98 and Windows Me Systems

Windows 98. To run the MATLAB add-in for Visual Studio on Windows 98 systems, add this line to your config.sys file:

```
shell=c:\command.com /e:32768 /p
```

Windows Me. To run the MATLAB add-in for Visual Studio on Windows Me systems, do the following:

1 Find C:\windows\system\conagent.exe in the Windows Explorer.
2 Right-click on the conagent.exe icon.
3 Select Properties from the context menu. This brings up the CONAGENT.EXE Properties window.
4 Select the Memory tab in the CONAGENT.EXE Properties window.
5 Set the Initial Environment field to 4096.
6 Click Apply.
7 Click OK.

For additional information on the MATLAB add-in for Visual Studio:
• See the MATLABAddin.hlp file in the <matlab>\bin\win32 directory, or
• Click on the Help icon in the MATLAB add-in for Visual Studio toolbar

Packaging Windows Applications for Distribution

To distribute a stand-alone Windows application, you must create a package containing these files:

• Your application executable.
• The contents, if any, of a directory named bin, created by mbuild in the same directory as your application executable. Note: mbuild does not create a bin directory for every stand-alone application.
• Any custom MEX-files your application uses.
• All the MATLAB run-time libraries.

For specific information about packaging these files, see “Distributing Stand-Alone Applications” on page 4-27.
Distributing Stand-Alone Applications

To make packaging an application easier, all the necessary MATLAB run-time libraries are prepackaged into a single, self-extracting archive file. For more information about how you can use this archive, see “Packaging the MATLAB Run-Time Libraries”. For information about how customers who receive your application can use this archive, see “Installing Your Application” on page 4-27.

Packaging the MATLAB Run-Time Libraries

All the MATLAB run-time libraries required by stand-alone applications are prepackaged into a single, self-extracting archive file, called the MATLAB Compiler Run-Time Library Installer. Instead of including all the run-time libraries individually in your stand-alone application distribution package, you can simply include this archive file.

The following table lists the name of the archive file for both UNIX and PC systems. In the table `<MATLAB>` represents your MATLAB installation directory and `<ARCH>` represents your UNIX platform.

<table>
<thead>
<tr>
<th>Platform</th>
<th>MATLAB Compiler Run-Time Library Installer</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX systems</td>
<td><code>&lt;MATLAB&gt;/extern/lib/&lt;ARCH&gt;/mglinstaller</code></td>
</tr>
<tr>
<td>PCs</td>
<td><code>&lt;MATLAB&gt;/extern/lib/win32/mglinstaller.exe</code></td>
</tr>
</tbody>
</table>

Installing Your Application

To install your application, your customers must

- Run the MATLAB Compiler Run-Time Library Installer. This program extracts the libraries from the archive and installs them in subdirectories of a directory specified by the user.
- Add the `bin/<ARCH>` subdirectory to their path. This is the only MATLAB Compiler Run-Time Library subdirectory that needs to be added to the path.
Note If customers already have the MATLAB math and graphics run-time libraries installed on their system, they do not need to reinstall them. They only need to ensure that the library search path is configured correctly.

On UNIX Systems
On UNIX systems, your customers run the MATLAB Compiler Run-Time Library Installer by executing the `mglinstaller` command at the system prompt. Your customers can specify the name of the directory into which they want to install the libraries. By default, the installer puts the files in the current directory.

After the installer unpacks and uncompresses the libraries, your customers must add the name of the `bin/<ARCH>` subdirectory to the `LD_LIBRARY_PATH` environment variable. (The equivalent variable on HP-UX systems is the `SHLIB_PATH` and `LIBPATH` on IBM AIX systems.)

For example, if customers working on a Linux system specify the installation directory `mgl_runtime_dir`, then they must add `mgl_runtime_dir/bin/glnx86` to the `LD_LIBRARY_PATH` environment variable.

On PCs
On PCs, your customers run the MATLAB Compiler Run-Time Library Installer by double-clicking on the `mglinstaller.exe` file. Your customers can specify the name of the directory into which they want to install the libraries. By default, the installer puts the files in the current directory.

After the installer unpacks and uncompresses the libraries, your customers must add the `bin\win32` subdirectory to the system path variable (`PATH`).

For example, if your customers specify the installation directory `mgl_runtime_dir`, then they must add `mgl_runtime_dir\bin\win32` to `PATH`.

Problem Starting Stand-Alone Application
Your application may compile successfully but fail when you or one of your customers tries to start it. If you run the application from a DOS command window, you or one of your customers may see an error message such as:
The ordinal #### could not be located in the dynamic-link library dforrt.dll.

To fix this problem, locate dforrt.dll or dford.dll in your Windows system directory and replace them with the corresponding files in the <MATLAB>\bin\win32 directory, where <MATLAB> represents the name of your MATLAB installation directory.

This same solution works for customers of your application who encounter the same problem. Your customers can replace these files in the Windows system directory with the corresponding versions in the <MGLRUNTIMELIBRARY>\bin\win32 directory, where <MGLRUNTIMELIBRARY> is the name of the directory in which they installed the MATLAB Compiler Run-Time Libraries.
Building Shared Libraries

You can use mbuild to build C shared libraries on both UNIX and the PC. All of the mbuild options that pertain to creating stand-alone applications also pertain to creating C shared libraries.

To create a C shared library, specify one or more files with the .exports extension. The .exports files are text files that contain the names of the functions to export from the shared library, one per line. You can include comments in your code by beginning a line (first column) with # or a *. mbuild treats these lines as comments and ignores them. mbuild merges multiple .exports files into one master exports list.

For example, given file1.exports as

```c
    times2
    times3
```

and file1.c as

```c
int times2(int x)
{
    return 2 * x;
}

int times3(int x)
{
    return 3 * x;
}
```

The command

```c
    mbuild file1.c file1.exports
```

creates a shared library named file1.ext, where ext is the platform-dependent shared library extension. For example, on the PC, it would be called file1.dll. The shared library exports the symbols times2 and times3.
Building COM Objects

**Note** To create COM components from the MATLAB Compiler, you must have the MATLAB COM Builder installed on your system.

You can use `mbuild` to create Component Object Model (COM) objects from MATLAB M-files. The collection of M-files is translated into a single COM class. MATLAB COM Builder supports multiple classes per component.

The interface to the COM class is the same set of functions that are exported from a C shared library, but the Compiler supports both C and C++ code generation in producing COM objects.

`mbuild` automatically:

- Invokes the Microsoft Interface Definition Language (MIDL) compiler
- Invokes the resource compiler
- Specifies the `.DEF` files

Using `mbuild` options you can enable auto registration of the COM-compatible DLL.

**Note** Creating COM objects from MATLAB M-files is available on Windows only. The only compilers that support the building of COM objects with the MATLAB Compiler are Borland C++Builder (versions 3.0, 4.0, and 5.0) and Microsoft Visual C/C++ (versions 5.0, 6.0, and 7.0).

For example, to compile `plus1.m` into a COM object, use

```
mcc -B 'ccom:addin,addin,1.0' plus1.m
```

For more information, see the MATLAB COM Builder documentation.
Building Excel Plug-Ins

**Note** To create Excel plug-ins from the MATLAB Compiler, you must have the MATLAB Excel Builder installed on your system.

You can use `mbuild` to create a COM object from MATLAB M-files that can be used as an Excel plug-in. The collection of M-files is translated into a single Excel plug-in. MATLAB Excel Builder supports one class per component.

The interface to the COM class is the same set of functions that are exported from a C shared library, but the Compiler supports both C and C++ code generation in producing COM objects.

`mbuild` automatically:

- Invokes the Microsoft Interface Definition Language (MIDL) compiler
- Invokes the resource compiler
- Specifies the `.DEF` files

Using `mbuild` options you can enable auto registration of the COM-compatible DLL.

**Note** Creating Excel plug-ins from MATLAB M-files is available on Windows only. The only compilers that support the building of Excel plug-ins with the MATLAB Compiler are Borland C++Builder (versions 3.0, 4.0, and 5.0) and Microsoft Visual C/C++ (versions 5.0, 6.0, and 7.0).

For example, to compile `plus1.m` into an Excel plug-in, use

```
mcc -B 'cexcel:addin,addin,1.0' plus1.m
```

For more information, see the MATLAB Excel Builder documentation.
Troubleshooting mbuild

This section identifies some of the more common problems that might occur when configuring mbuild to create stand-alone applications.

Options File Not Writeable. When you run mbuild - setup, mbuild makes a copy of the appropriate options file and writes some information to it. If the options file is not writeable, you are asked if you want to overwrite the existing options file. If you choose to do so, the existing options file is copied to a new location and a new options file is created.

Out of Environment Space Running mex or mbuild. On Windows 98 systems, the mex and mbuild scripts require more than the default amount of environment space. If you get the error, out of environment space, add this line to your config.sys file:

```
shell=c:\command.com /e:32768 /p
```

On Windows Me systems, if you encounter this problem and are using the MATLAB add-in for Visual Studio, follow the procedure in “Configuring on Windows 98 and Windows Me Systems” on page 4-25.

Directory or File Not Writeable. If a destination directory or file is not writeable, ensure that the permissions are properly set. In certain cases, make sure that the file is not in use.

mbuild Generates Errors. On UNIX, if you run mbuild filename and get errors, it may be because you are not using the proper options file. Run mbuild -setup to ensure proper compiler and linker settings.

Compiler and/or Linker Not Found. On PCs running Windows, if you get errors such as unrecognized command or file not found, make sure the command line tools are installed and the path and other environment variables are set correctly in the options file.

mbuild Not a Recognized Command. If mbuild is not recognized, verify that <MATLAB>\bin is on your path. On UNIX, it may be necessary to rehash.
mbuild Works from Shell but Not from MATLAB (UNIX). If the command

`mbuild ex1.c`

works from the UNIX command prompt but does not work from the MATLAB prompt, you may have a problem with your `.cshrc` file. When MATLAB launches a new C shell to perform compilations, it executes the `.cshrc` script. If this script causes unexpected changes to the `PATH` environment variable, an error may occur. You can test this by performing a

```
set SHELL=/bin/sh
```

prior to launching MATLAB. If this works correctly, then you should check your `.cshrc` file for problems setting the `PATH` environment variable.

Cannot Locate Your Compiler (PC). If `mbuild` has difficulty locating your installed compilers, it is useful to know how it goes about finding compilers. `mbuild` automatically detects your installed compilers by first searching for locations specified in the following environment variables:

- `BORLAND` for Borland C/C++, Version 5.3
- `MSVCDIR` for Microsoft Visual C/C++, Version 5.0, 6.0, or 7.0

Next, `mbuild` searches the Windows registry for compiler entries.

Internal Error When Using `mbuild -setup` (PC). Some antivirus software packages such as Cheyenne AntiVirus and Dr. Solomon may conflict with the `mbuild -setup` process. If you get an error message during `mbuild -setup` of the following form

```
mex.bat: internal error in sub get_compiler_info(): don't recognize <string>
```

then you need to disable your antivirus software temporarily and rerun `mbuild -setup`. After you have successfully run the setup option, you can reenable your antivirus software.

Verification of `mbuild` Fails. If none of the previous solutions addresses your difficulty with `mbuild`, contact Technical Support at The MathWorks at support@mathworks.com.
Troubleshooting the Compiler

Typically, problems that occur when building stand-alone C and C++ applications involve `mbuild`. However, it is possible that you may run into some difficulty with the MATLAB Compiler. One problem that might occur when you try to generate a stand-alone application involves licensing.

**Licensing Problem.** If you do not have a valid license for the MATLAB Compiler, you will get an error message similar to the following when you try to access the Compiler:

```
Error: Could not check out a Compiler License:  
No such feature exists.
```

If you have a licensing problem, contact The MathWorks. A list of contacts at The MathWorks is provided at the beginning of this manual.

**MATLAB Compiler Does Not Generate Application.** If you experience other problems with the MATLAB Compiler, contact Technical Support at The MathWorks at support@mathworks.com.

**Missing Functions In Callbacks.** If your application includes a call to a function in a callback string or in a string passed as an argument to the `feval` function or an ODE solver, and this is the only place in your M-file this function is called, the Compiler will not compile the function. The Compiler does not look in these text strings for the names of functions to compile. See “Fixing Callback Problems: Missing Functions” on page 1-20 for more information.
Coding with M-Files Only

One way to create a stand-alone application is to write all the source code in one or more M-files or MEX-files. Coding an application in M-files allows you to take advantage of the MATLAB interpretive development environment. Then, after getting the M-file version of your program working properly, compile the code and build it into a stand-alone application.

Note  It is good practice to avoid manually modifying the C or C++ code that the MATLAB Compiler generates. If the generated C or C++ code is not to your liking, modify the M-file (and/or the compiler options) and then recompile. If you do edit the generated C or C++ code, remember that your changes will be erased the next time you recompile the M-file. For more information, see “Compiling MATLAB Provided M-Files Separately” on page 4-40 and “Interfacing M-Code to C/C++ Code” on page 5-46.

Consider a very simple application whose source code consists of two M-files, mrank.m and main.m. This example involves C code; you use a similar process (described below) for C++ code. In this example, the line r = zeros(n,1) preallocates memory to help the performance of the Compiler.

mrank.m returns a vector of integers, r. Each element of r represents the rank of a magic square. For example, after the function completes, r(3) contains the rank of a 3-by-3 magic square:

```matlab
function r = mrank(n)
    r = zeros(n,1);
    for k = 1:n
        r(k) = rank(magic(k));
    end
```

main.m contains a “main routine” that calls mrank and then prints the results:

```matlab
function main
    r = mrank(5)
```

To compile these into code that can be built into a stand-alone application, invoke the MATLAB Compiler:

```bash
mcc -mc main mrank
```
The -m option flag causes the MATLAB Compiler to generate C source code suitable for stand-alone applications. For example, the MATLAB Compiler generates C source code files `main.c`, `main_main.c`, and `mrank.c`. `main_main.c` contains a C function named `main`; `main.c` and `mrank.c` contain a C functions named `mlfMain` and `mlfMrank`. (The -c option flag inhibits invocation of `mbuild`.)

To build an executable application, you can use `mbuild` to compile and link these files. Or, you can automate the entire build process (invoke the MATLAB Compiler twice, use `mbuild` to compile the files with your ANSI C compiler, and link the code) by using the command

```
mcc -m main mrank
```

Figure 4-2, Building Two M-Files into a Stand-Alone C Application, illustrates the process of building a stand-alone C application from two M-files. The commands to compile and link depend on the operating system being used. See “Building Stand-Alone C/C++ Applications” on page 4-4 for details.
Figure 4-2: Building Two M-Files into a Stand-Alone C Application
For C++ code, add `-L cpp` to the previous commands and use a C++ compiler instead of a C compiler.
Alternative Ways of Compiling M-Files

The previous section showed how to compile `main.m` and `mrank.m` separately. This section explores two other ways of compiling M-files.

**Note** These two alternative ways of compiling M-files apply to C++ as well as to C code; the only difference is that you add `-L cpp` for C++.

Compiling MATLAB Provided M-Files Separately

The M-file `mrank.m` contains a call to `rank`. The MATLAB Compiler translates the call to `rank` into a C call to `mlfRank`. The `mlfRank` routine is part of the MATLAB M-File Math Library. The `mlfRank` routine behaves in stand-alone applications exactly as the `rank` function behaves in the MATLAB interpreter. However, if this default behavior is not desirable, you can create your own version of `rank` or `mlfRank`.

One way to create a new version of `rank` is to copy the MATLAB source code for `rank` and then to edit this copy. MATLAB implements `rank` as the M-file `rank.m` rather than as a built-in command. To see the MATLAB code for `rank.m`, enter

```
type rank
```

Copy this code into a file named `rank.m` located in the same directory as `mrank.m` and `main.m`. Then, modify your version of `rank.m`. After completing the modifications, compile `rank.m`:

```
mcc -t rank
```

Compiling `rank.m` generates file `rank.c`, which contains a function named `mlfRank`. Then, compile the other M-files composing the stand-alone application.

```
mcc -t main.m          (produces main.c)  
mcc -t mrank.m         (produces mrank.c)  
mcc -W main main mrank rank.m   (produces main_main.c)
```

To compile and link all four C source code files (`main.c`, `rank.c`, `mrank.c`, and `main_main.c`) into a stand-alone application, use
mcc -m main_main.c main.c rank.c mrank.c

The resulting stand-alone application uses your customized version of mlfRank rather than the default version of mlfRank stored in the MATLAB M-File Math Library.

**Note** On PCs running Windows, as well as SGI, SGI64, and IBM, if a function in the MATLAB M-File Math Library calls mlfRank, it will call the one found in the Library and not your customized version. We recommend that you call your version of rank something else, for example, myrank.m.

---

**Compiling mrank.m and rank.m as Helper Functions**

Another way of building the mrank stand-alone application is to compile rank.m and mrank.m as helper functions to main.m. In other words, instead of invoking the MATLAB Compiler three separate times, invoke the MATLAB Compiler only once. For C

```bash
mcc -m main rank
```

For C++

```bash
mcc -p main rank
```

These commands create files containing the C or C++ source code. The macro options -m and -p automatically compile all helper functions.
Mixing M-Files and C or C++

The examples in this section illustrate how to mix M-files and C or C++ source code files:

- The first example is a simple application that mixes M-files and C code.
- The second example illustrates how to write C code that calls a compiled M-file.

One way to create a stand-alone application is to code some of it as one or more function M-files and to code other parts directly in C or C++. To write a stand-alone application this way, you must know how to

- Call the external C or C++ functions generated by the MATLAB Compiler.
- Handle the results these C or C++ functions return.

**Note** If you include compiled M code into a larger application, you must produce a library wrapper file even if you do not actually create a separate library. For more information on creating libraries, see the library sections in “Supported Executable Types” on page 5-21.

Simple Example

This example involves mixing M-files and C code. Consider a simple application whose source code consists of `mrank.m` and `mrankp.c`.

**mrank.m**

`mrank.m` contains a function that returns a vector of the ranks of the magic squares from 1 to `n`:

```matlab
function r = mrank(n)
    r = zeros(n,1);
    for k = 1:n
        r(k) = rank(magic(k));
    end
```
The Build Process
The steps needed to build this stand-alone application are

1 Compile the M-code.

2 Generate the library wrapper file.

To perform these steps, use

```
mcc -t -W lib:Pkg -T:link:exe -h mrank mrankp.c libmmfile.mlib
```

The MATLAB Compiler generates C source code files named `mrank.c`, `Pkg.c`, and `Pkg.h`. This command invokes `mbuild` to compile the resulting Compiler-generated source files (`mrank.c`, `Pkg.c`, `Pkg.h`) with the existing C source file (`mrankp.c`) and links against the required libraries. For details, see “Building Stand-Alone C/C++ Applications” on page 4-4.

The MATLAB Compiler provides two different versions of `mrankp.c` in the `<matlab>/extern/examples/compiler` directory:

- `mrankp.c` contains a POSIX-compliant `main` function. `mrankp.c` sends its output to the standard output stream and gathers its input from the standard input stream.
- `mrankwin.c` contains a Windows version of `mrankp.c`. 
Figure 4-3: Mixing M-Files and C Code to Form a Stand-Alone Application
mrankp.c
The code in mrankp.c calls mrank and outputs the values that mrank returns:

```c
#include <stdio.h>
#include <math.h>
#include "matlab.h"
/* Prototype for mlfMrank */
extern mxArray *mlfMrank( mxArray * );

main( int argc, char **argv )
{
    mxArray *N;    /* Matrix containing n. */
    mxArray *R;    /* Result matrix. */
    int      n;    /* Integer parameter from command line. */

    /* Get any command line parameter. */
    if (argc >= 2) {
        n = atoi(argv[1]);
    } else {
        n = 12;
    }
    PkgInitialize(); /* Initialize the library of M-Functions */

    /* Create a 1-by-1 matrix containing n. */
    N = mlfScalar(n);

    /* Call mlfMrank, the compiled version of mrank.m */
    R = mlfMrank(N);
```
/* Print the results. */
mlfPrintMatrix(R);

/* Free the matrices allocated during this computation. */
mxDestroyArray(N);
mxDestroyArray(R);

PkgTerminate();    /* Terminate the library of M-functions */
}

An Explanation of mrankp.c

The heart of mrankp.c is a call to the mlfMrank function. Most of what comes before this call is code that creates an input argument to mlfMrank. Most of what comes after this call is code that displays the vector that mlfMrank returns. First, the code must call the Compiler-generated library initialization function.

PkgInitialize();/* Initialize the library of M-Functions */

To understand how to call mlfMrank, examine its C function header, which is

```
mxArray *mlfMrank(mxArray *n_rhs_)
```

According to the function header, mlfMrank expects one input parameter and returns one value. All input and output parameters are pointers to the mxArray data type. (See “External Interfaces/API” in the MATLAB online documentation for details on the mxArray data type.) To create and manipulate mxArray * variables in your C code, you can call the mx routines described in the “External Interfaces/API” or any routine in the MATLAB C/C++ Math Library. For example, to create a 1-by-1 mxArray * variable named N with real data, mrankp calls mlfScalar:

```
N = mlfScalar(n);
```

mrankp can now call mlfMrank, passing the initialized N as the sole input argument.

```
R = mlfMrank(N);
```

mlfMrank returns a pointer to an mxArray * variable named R. The easiest way to display the contents of R is to call the mlfPrintMatrix convenience function:

```
mlfPrintMatrix(R);
```
mlfPrintMatrix is one of the many routines in the MATLAB Math Built-In Library, which is part of the MATLAB Math Library.

Finally, mrankp must free the heap memory allocated to hold matrices and call the Compiler-generated termination function:

```c
mxDestroyArray(N);
mxDestroyArray(R);
PkgTerminate();/* Terminate the library of M-functions */
```

### Advanced C Example

This section illustrates an advanced example of how to write C code that calls a compiled M-file. Consider a stand-alone application whose source code consists of two files:

- `multarg.m`, which contains a function named `multarg`
- `multargp.c`, which contains a C function named `main`

`multarg.m` specifies two input parameters and returns two output parameters:

```matlab
function [a,b] = multarg(x,y)
a = (x + y) * pi;
b = svd(svd(a));
```

The code in `multargp.c` calls `mlfMultarg` and then displays the two values that `mlfMultarg` returns.

```c
#include <stdio.h>
#include <string.h>
#include <math.h>
#include "matlab.h"
#include "multpkg.h"/* Include Compiler-generated header file */

static void PrintHandler( const char *text )
{
    printf(text);
}

int main( ) /* Programmer written coded to call mlfMultarg */
{
    #define ROWS  3
    #define COLS  3
```

```c
    #include <stdio.h>
    #include <string.h>
    #include <math.h>
    #include "matlab.h"
    #include "multpkg.h"/* Include Compiler-generated header file */

    static void PrintHandler( const char *text )
    {
        printf(text);
    }

    int main( ) /* Programmer written coded to call mlfMultarg */
    {
        #define ROWS  3
        #define COLS  3
```

```c
    // ... code continues here ...
```
mxArray *a, *b, *x, *y;
double x_pr[ROWS * COLS] = {1, 2, 3, 4, 5, 6, 7, 8, 9};
double x_pi[ROWS * COLS] = {9, 2, 3, 4, 5, 6, 7, 8, 1};
double y_pr[ROWS * COLS] = {1, 2, 3, 4, 5, 6, 7, 8, 9};
double y_pi[ROWS * COLS] = {2, 9, 3, 4, 5, 6, 7, 1, 8};
double *a_pr, *a_pi, value_of_scalar_b;
multpkgInitialize(); /* Call multpkg initialization */
/* Install a print handler to tell mlfPrintMatrix how to display its output. */
mlfSetPrintHandler(PrintHandler);
/* Create input matrix "x" */
x = mxCreateDoubleMatrix(ROWS, COLS, mxCOMPLEX);
memcpy(mxGetPr(x), x_pr, ROWS * COLS * sizeof(double));
memcpy(mxGetPi(x), x_pi, ROWS * COLS * sizeof(double));

/* Create input matrix "y" */
y = mxCreateDoubleMatrix(ROWS, COLS, mxCOMPLEX);
memcpy(mxGetPr(y), y_pr, ROWS * COLS * sizeof(double));
memcpy(mxGetPi(y), y_pi, ROWS * COLS * sizeof(double));

/* Call the mlfMultarg function. */
a = (mxArray *)mlfMultarg(&b, x, y);

/* Display the entire contents of output matrix "a". */
mlfPrintMatrix(a);

/* Display the entire contents of output scalar "b" */
mlfPrintMatrix(b);

/* Deallocate temporary matrices. */
mxDestroyArray(a);
mxDestroyArray(b);
multpkgTerminate(); /* Call multpkg termination */
return(0);
You can build this program into a stand-alone application by using the command

```
mcc -t -W lib:multpkg -T link:exe multarg multargp.c
libmmfile.mlib
```

The program first displays the contents of a 3-by-3 matrix $a$ and then displays the contents of scalar $b$:

```
6.2832 +34.5575i  25.1327 +25.1327i  43.9823 +43.9823i
12.5664 +34.5575i  31.4159 +31.4159i  50.2655 +28.2743i
18.8496 +18.8496i  37.6991 +37.6991i  56.5487 +28.2743i

143.4164
```

**An Explanation of This C Code**

Invoking the MATLAB Compiler on `multarg.m` generates the C function prototype:

```
extern mxArray * mlfMultarg(mxArray * * b, mxArray * x, mxArray * y);
extern void mlxMultarg(int nlhs, mxArray * plhs[], int nrhs, mxArray * prhs[]);
```

This C function header shows two input arguments (mxArray *x and mxArray *y) and two output arguments (the return value and mxArray **b).

Use `mxCreateDoubleMatrix` to create the two input matrices (x and y). Both x and y contain real and imaginary components. The `memcpy` function initializes the components, for example:

```
x = mxCreateDoubleMatrix(ROWS, COLS, COMPLEX);
memcpy(mxGetPr(x), x_pr, ROWS * COLS * sizeof(double));
memcpy(mxGetPi(y), y_pi, ROWS * COLS * sizeof(double));
```

The code in this example initializes variable x from two arrays (x_pr and x_pi) of predefined constants. A more realistic example would read the array values from a data file or a database.

After creating the input matrices, `main` calls `mlfMultarg`:

```
a = (mxArray *)mlfMultarg(&b, x, y);
```
The `mlfMultarg` function returns matrices `a` and `b`. `a` has both real and imaginary components; `b` is a scalar having only a real component. The program uses `mlfPrintMatrix` to output the matrices, for example:

```mlf
mlfPrintMatrix(a);
```
Controlling Code Generation

This chapter describes the code generated by the MATLAB Compiler and the options that you can use to control code generation.

- Code Generation Overview (p. 5-2) Sample source files and generated filenames
- Compiling Private and Method Functions (p. 5-5) Working with private and method functions
- The Generated Header Files (p. 5-8) Generated C and C++ header files
- Internal Interface Functions (p. 5-11) Generated C and C++ interface functions
- Supported Executable Types (p. 5-21) Generated wrapper functions
- Formatting Compiler-Generated Code (p. 5-35) Controlling the look of generated C/C++ code
- Including M-File Information in Compiler Output (p. 5-40) Controlling annotation in generated C/C++ code
- Interfacing M-Code to C/C++ Code (p. 5-46) Calling C/C++ functions from M-code
Code Generation Overview

Example M-Files
To generate the various files created by the Compiler, this chapter uses several different M-files — gasket.m, foo.m, fun.m, and sample.m.

Sierpinski Gasket M-File
function theImage = gasket(numPoints)
    %GASKET An image of a Sierpinski Gasket.
    % IM = GASKET(NUMPOINTS)
    %
    % Example:
    % x = gasket(50000);
    % imagesc(x);colormap([0 0 0;1 1 1]);
    % axis equal tight
    %
    % Copyright (c) 1984-98 by The MathWorks, Inc
    % $Revision: 1.1 $  $Date: 1998/09/11 20:05:06 $

    theImage = zeros(1000,1000);
    corners = [866 1;1 500;866 1000];
    startPoint = [866 1];
    theRand = rand(numPoints,1);
    theRand = ceil(theRand*3);
    for i=1:numPoints
        startPoint = floor((corners(theRand(i),:)+startPoint)/2);
        theImage(startPoint(1),startPoint(2)) = 1;
    end

foo M-File
function [a, b] = foo(x, y)
    if nargin == 0
    elseif nargin == 1
        a = x;
    elseif nargin == 2
        a = x;
b = y;
end

fun M-File
function a = fun(b)
a(1) = b(1) .* b(1);
a(2) = b(1) + b(2);
a(3) = b(2) / 4;

sample M-File
function y = sample( varargin )
varargin{:}
y = 0;

Generated Code
This chapter investigates the generated header files, interface functions, and wrapper functions for the C MEX, stand-alone C and C++ targets, and C and C++ libraries.

When you use the MATLAB Compiler to compile an M-file, it generates these files:

- C or C++ code, depending on your target language (-L) specification
- Header file
- Wrapper file, depending on the -W option

The C or C++ code that is generated by the Compiler and the header file are independent of the final target type and target platform. That is, the C or C++ code and header file are identical no matter what the desired final output. The wrapper file provides the code necessary to support the output executable type. So, the wrapper file is different for each executable type.

Table 5-1, Compiler-Generated Files, shows the names of the files generated when you compile a generic M-file Table 5-1(file.m) for the MEX and stand-alone targets. The table also shows the files generated when you compile a set of files (filelist) for the library target and the COM target.
Controlling Code Generation

Note Many of the code snippets generated by the MATLAB Compiler that are used in this chapter use the -F page-width option to produce readable code that fits nicely on the book’s printed page. For more information about the page-width option, see “Formatting Compiler-Generated Code” on page 5-35.
Compiling Private and Method Functions

Private functions are functions that reside in subdirectories with the special name `private`, and are visible only to functions in the parent directory. Since private functions are invisible outside of the parent directory, they can use the same names as functions in other directories. Because MATLAB looks for private functions before standard M-file functions, it will find a private function before a nonprivate one.

Method functions are implementations specific to a particular MATLAB type or user-defined object. Method functions are only invoked when the argument list contains an object of the correct class.

In order to compile a method function, you must specify the name of the method along with the classname so that the Compiler can differentiate the method function from a nonmethod (normal) function.

**Note** Although MATLAB Compiler 3.0 can currently compile method functions, it does not support overloading of methods as implemented in MATLAB. This feature is provided in anticipation of support of overloaded methods being added.

Method directories can contain private directories. Private functions are found only when executing a method from the parent method directory. Taking all of this into account, the Compiler command line needs to be able to differentiate between these various functions that have the same name. A file called `foo.m` that contains a function called `foo` can appear in all of these locations at the same time. The conventions used on the Compiler command line are documented in this table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>foo.m</code></td>
<td>Default version of <code>foo.m</code></td>
</tr>
<tr>
<td><code>xxx/private/foo.m</code></td>
<td><code>foo.m</code> private to the <code>xxx</code> directory</td>
</tr>
</tbody>
</table>
Controlling Code Generation

This table lists the functions you can specify on the command line and their corresponding function and filenames.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@cell/foo.m</td>
<td>foo.m method to operate on cell arrays</td>
</tr>
<tr>
<td>@cell/private/foo.m</td>
<td>foo.m private to methods that operate on cell arrays</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Function</th>
<th>C Function</th>
<th>C++ Function</th>
<th>Filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>mlfFoo</td>
<td>foo</td>

</tr>
<tr>
<td></td>
<td>mlfNcell_private_Foo</td>
<td>mlxCell_private_foo</td>
<td>_cell_private_foo.hpp</td>
</tr>
</tbody>
</table>

For private functions, the name given in the table above may be ambiguous. The MATLAB Compiler generates a warning when it cannot distinguish which private function to use. For example, given these two foo.m private functions and their locations

/Z/X/private/foo.m
/Y/X/private/foo.m

the Compiler searches up only one level and determines the path to the file as X/private/foo.m
Since it is ambiguous which `foo.m` you are requesting, it generates the warning

Warning: The specified private directory is not unique. Both /Z/X/private and /Y/X/private are found on the path for this private directory.
The Generated Header Files

This section highlights the two header files that the Compiler can generate for the Sierpinski Gasket (gasket.m) example.

C Header File

If the target language is C, the Compiler generates the header file, gasket.h. This example uses the Compiler command

```
mcc -t -L C -T codegen -F page-width:60 gasket
```

to generate the associated files. The C header file, gasket.h, is

```
/*
 * MATLAB Compiler: 3.0
 * Date: Wed Jan 23 14:51:45 2002
 * Arguments: "-B" "macro_default" "-O" "all" "-O"
 * "fold_scalar_mxarrays:on" "-O"
 * "fold_non_scalar_mxarrays:on" "-O"
 * "optimize_integer_for_loops:on" "-O" "array_indexing:on"
 * "-O" "optimize_conditionals:on" "-t" "-L" "C" "-T"
 * "codegen" "-F" "page-width:60" "gasket"
*/

#ifndef MLF_V2
#define MLF_V2 1
#endif

#ifndef __gasket_h
#define __gasket_h 1
#endif

#ifdef __cplusplus
extern "C" {
#endif

#include "libmatlb.h"

extern void InitializeModule_gasket(void);
extern void TerminateModule_gasket(void);
extern _mexLocalFunctionTable _local_function_table_gasket;
```
The Generated Header Files

extern mxArray * mlfGasket(mxArray * numPoints);
extern void mlxGasket(int nlhs,
    mxArray * plhs[],
    int nrhs,
    mxArray * prhs[]);

#ifdef __cplusplus
}
#endif
#endif

C++ Header File

If the target language is C++, the Compiler generates the header file, 
gasket.hpp. This example uses the Compiler command

```
mcc -t -L Cpp -T codegen -F page-width:60 gasket
```

to generate the associated files. The C++ header file, gasket.hpp, is

```
#ifndef __gasket_hpp
#define __gasket_hpp

#include "libmatlb.hpp"

extern void InitializeModule_gasket();
extern void TerminateModule_gasket();
extern _mexLocalFunctionTable _local_function_table_gasket;
```

5-9
extern mwArray gasket(mwArray numPoints = mwArray::DIN);
#ifdef __cplusplus
extern "C"
#endif
void mlxGasket(int nlhs,
               mxArray * plhs[],
               int nrhs,
               mxArray * prhs[]);
#endif
Internal Interface Functions

This section uses the Sierpinski Gasket example (gasket.m) to show several of the generated interface functions for the C and C++ cases. The remaining interface functions are generated by the example foo.m as described earlier in this chapter.

Interface functions perform argument translation between the standard calling conventions and the Compiler-generated code.

C Interface Functions

The C interface functions process any input arguments and pass them to the implementation version of the function, Mf.

mlxF Interface Function

The Compiler always generates the mlxF interface function, which is used by feval. At times, the Compiler needs to use feval to perform argument matching even if the user does not specifically call feval. For example,

```matlab
x = cell(1,5);
y = [1 2 3 4 5];
[x{:}] = deal(y{:});
```

would use the feval interface. The following C code is the corresponding feval interface (mlxGasket) from the Sierpinski Gasket example. This function calls the C Mgasket function.

Note Comments have been added to the generated code to highlight where the input and output arguments are processed and where functions are called.

```c
/*
 * The function "mlxGasket" contains the feval interface
 * for the "gasket" M-function from file
 * "<matlab>\extern\examples\compiler\gasket.m" (lines 1-23).
 * The feval function calls the implementation version of
 * gasket through this function. This function processes
 * any input arguments and passes them to the
 * implementation version of the function, appearing above.
*/
```
void mlxGasket(int nlhs,
    mxArray * plhs[],
    int nrhs,
    mxArray * prhs[]) {
    mxArray * mprhs[1];
    mxArray * mplhs[1];
    int i;
    /* ------------- Input Argument Processing ------------- */
    if (nlhs > 1) {
        mlfError(
            mxCreateString(
                "Run-time Error: File: gasket Line: 1 Column: ",
                NULL);
        }
    if (nrhs > 1) {
        mlfError(
            mxCreateString(
                "Run-time Error: File: gasket Line: 1 Column: ",
                NULL);
        }
    for (i = 0; i < 1; ++i) {
        mplhs[i] = NULL;
    }
    for (i = 0; i < 1 && i < nrhs; ++i) {
        mprhs[i] = prhs[i];
    }
    for (; i < 1; ++i) {
        mprhs[i] = NULL;
    }
    /* ------------- Call to C Implementation Function --------- */
    mlfEnterNewContext(0, 1, mprhs[0]);
}
/* ------------- Output Argument Processing ------------- */
mlfRestorePreviousContext(0, 1, mprhs[0]);
plhs[0] = mplhs[0];
}

**mlfF Interface Function**
The Compiler always generates the mlfF interface function, which contains the "normal" C interface to the function. This code is the corresponding C interface function (mlfGasket) from the Sierpinski Gasket example. This function calls the C mgasket function:

```c
mxArray * mlfGasket(mxArray * numPoints) {
    int nargout = 1;
    /* ------------- Input Argument Processing ------------- */
    mxArray * theImage = NULL;
    mlfEnterNewContext(0, 1, numPoints);
    /* ------------- Call M-Function ------------- */
    theImage = Mgasket(nargout, numPoints);
    /* ------------- Output Argument Processing ------------- */
    mlfRestorePreviousContext(0, 1, numPoints);
    return mlfReturnValue(theImage);
}
```

**mlfNF Interface Function**
The Compiler produces this interface function only when the M-function uses the variable nargout. The nargout interface allows you to specify the number of requested outputs via the int nargout argument, as opposed to the normal interface that dynamically calculates the number of outputs based on the number of non-NULL inputs it receives.
This is the corresponding `mlfNF` interface function (mlfNFoo) for the `foo.m` example described earlier in this chapter. This function calls the `Mfoo` function that appears in `foo.c`:

```c
/*
 * The function "mlfNFoo" contains the nargout interface
 * for the "foo" M-function from file
 * "<matlab>\extern\examples\compiler\foo.m" (lines 1-8).
 * This interface is only produced if the M-function uses
 * the special variable "nargout". The nargout interface
 * allows the number of requested outputs to be specified
 * via the nargout argument, as opposed to the normal
 * interface, which dynamically calculates the number of
 * outputs based on the number of non-NULL inputs it
 * receives. This function processes any input arguments
 * and passes them to the implementation version of the
 * function, appearing above.
 */

mxArray * mlfNFoo(int nargout,
        mxArray ** b,
        mxArray * x,
        mxArray * y) {
/* ------------- Input Argument Processing ------------ */
    mxArray * a = NULL;
    mxArray * b__ = NULL;
    mlfEnterNewContext(1, 2, b, x, y);
/* ----------------- Call M-Function ------------------ */
    a = Mfoo(&b__, nargout, x, y);
/* ------------- Output Argument Processing ----------- */
    mlfRestorePreviousContext(1, 2, b, x, y);
    if (b != NULL) {
        mclCopyOutputArg(b, b__);
    } else {
        mxDestroyArray(b__);}
    return mlfReturnValue(a);
}
```
mlfVF Interface Function

The Compiler produces this interface function only when the M-function uses the variable \texttt{nargout} and has at least one output. This \texttt{void} interface function specifies zero output arguments to the implementation version of the function, and in the event that the implementation version still returns an output (which, in MATLAB, would be assigned to the \texttt{ans} variable), it deallocates the output.

This is the corresponding \texttt{mlfVF} interface function (\texttt{mlfVFoo}) for the \texttt{foo.m} example described at the beginning of this section. This function calls the C \texttt{Mfoo} implementation function that appears in \texttt{foo.c}:

```c
/*
 * The function "mlfVFoo" contains the void interface for
 * the "foo" M-function from file
 * "<matlab>\extern\examples\compiler\foo.m" (lines 1-8). The
 * void interface is only produced if the M-function uses
 * the special variable "nargout", and has at least one
 * output. The void interface function specifies zero
 * output arguments to the implementation version of the
 * function, and in the event that the implementation
 * version still returns an output (which, in MATLAB, would
 * be assigned to the "ans" variable), it deallocates the
 * output. This function processes any input arguments and
 * passes them to the implementation version of the
 * function, appearing above.
 */
void mlfVFoo(mxArray * x, mxArray * y) {
    /* ------------- Input Argument Processing ------------ */
    mxArray * a = NULL;
    mxArray * b = NULL;
    mlfEnterNewContext(0, 2, x, y);
    /* ----------------- Call M-Function ------------------ */
    a = Mfoo(&b, 0, x, y);
    /* ------------- Output Argument Processing ----------- */
    mlfDestroyPreviousContext(0, 2, x, y);
    mxDestroyArray(a);
    mxDestroyArray(b);
}
```
C++ Interface Functions

The C++ interface functions process any input arguments and pass them to the implementation version of the function.

**Note** In C++, the mlxF interface functions are also C functions in order to allow the feval interface to be uniform between C and C++.

**mlxF Interface Function**

The Compiler always generates the mlxF interface function, which is used by feval. At times, the Compiler needs to use feval to perform argument matching even if the user does not specifically call feval. For example,

```matlab
x = cell(1,5);
y = {1 2 3 4 5};
[x{:}] = deal(y{:});
```

would use the feval interface. The following C++ code is the corresponding feval interface (mlxGasket) from the Sierpinski Gasket example. This function calls the C++ Mgasket function:

```c
void mlxGasket(int nlhs,
               mxArray * plhs[],
               int nrhs,
               mxArray * prhs[]) {
  MW_BEGIN_MLX();

  // ------------- Input Argument Processing ---------------
  mwArray mprhs[1];
  mwArray mplhs[1];
```
int i;
mclCppUndefineArrays(1, mplhs);
if (nlhs > 1) {
    error(
        mwVarargin(
            mwArray(
                "Run-time Error: File: gasket Line:"
                " 1 Column: 1 The function "gasket"
                " was called with more than the d"
                "eclared number of outputs (1).")));}
if (nrhs > 1) {
    error(
        mwVarargin(
            mwArray(
                "Run-time Error: File: gasket Line:"
                " 1 Column: 1 The function "gasket"
                " was called with more than the d"
                "eclared number of inputs (1)."));}
for (i = 0; i < 1 && i < nrhs; ++i) {
    mprhs[i] = mwArray(prhs[i], 0);
}
for (; i < 1; ++i) {
    mprhs[i].MakeDIN();
}
// --------------- Call M-Function ---------------
    mplhs[0] = Mgasket(nlhs, mprhs[0]);
// --------------- Output Argument Processing ---------------
    plhs[0] = mplhs[0].FreezeData();
MW_END_MLX();

F Interface Function
The Compiler always generates the F interface function, which contains the "normal" C++ interface to the function. This code is the corresponding C++ interface function (gasket) from the Sierpinski Gasket example. This function calls the C++ code:
The function "gasket" contains the normal interface for
the "gasket" M-function from file
"<matlab>\extern\examples\compiler\gasket.m" (lines 1-23).
This function processes any input arguments and passes
them to the implementation version of the function,
appearing above.

```c++
mwArray gasket(mwArray numPoints) {
    int nargout = 1;
    mwArray theImage = mwArray::UNDEFINED;
    // ----------------- Call M-Function ---------------------
    theImage = Mgasket(nargout, numPoints);
    // ------------- Output Argument Processing -------------
    return theImage;
}
```

**NF Interface Function**

The Compiler produces this interface function only when the M-function uses
the variable nargout. The nargout interface allows the number of requested
outputs to be specified via the nargout argument, as opposed to the normal
interface that dynamically calculates the number of outputs based on the
number of non-NULL inputs it receives.

This is the corresponding NF interface function (NFoo) for the foo.m example
described earlier in this chapter. This function calls the Mfoo function
appearing in foo.cpp:

```c++
//
// The function "Nfoo" contains the nargout interface for
// the "foo" M-function from file
// "<matlab>\extern\examples\compiler\foo.m" (lines 1-8).
// This interface is only produced if the M-function uses
// the special variable "nargout". The nargout interface
// allows the number of requested outputs to be specified
// via the nargout argument, as opposed to the normal
// interface, which dynamically calculates the number of
// outputs based on the number of non-NULL inputs it
// receives. This function processes any input arguments
// and passes them to the implementation version of the
```
// function, appearing above.
//
mwArray Nfoo(int nargout,
        mwArray * b,
        mwArray x,
        mwArray y) {
// ------------- Input Argument Processing -------------
    mwArray a = mwArray::UNDEFINED;
    mwArray b__ = mwArray::UNDEFINED;
// ------------- Call M-Function ---------------------
    a = Mfoo(&b__, nargout, x, y);
// ------------- Input Argument Processing -------------
    if (b != NULL) {
        *b = b__;
    }
// ------------- Output Argument Processing -------------
    return a;
}
VF Interface Function

The Compiler produces this interface function only when the M-function uses the variable nargout and has at least one output. The void interface function specifies zero output arguments to the implementation version of the function, and in the event that the implementation version still returns an output (which, in MATLAB, would be assigned to the ans variable), it deallocates the output.

This is the corresponding VF interface function (VFoo) for the foo.m example described earlier in this chapter. This function calls the Mfoo function appearing in foo.cpp:

```c
// The function "Vfoo" contains the void interface for the
// "foo" M-function from file
// "<matlab>
// The void interface is only produced if the M-function
// uses the special variable "nargout", and has at least
// one output. The void interface function specifies zero
// output arguments to the implementation version of the
// function, and in the event that the implementation
// version still returns an output (which, in MATLAB, would
// be assigned to the "ans" variable), it deallocates the
// output. This function processes any input arguments and
// passes them to the implementation version of the
// function, appearing above.
//
void Vfoo(mwArray x, mwArray y) {
    mwArray a = mwArray::UNDEFINED;
    mwArray b = mwArray::UNDEFINED;
    a = Mfoo(&b, 0, x, y);
}
```
**Supported Executable Types**

Wrapper functions create a link between the Compiler-generated code and a supported executable type by providing the required interface that allows the code to operate in the desired execution environment.

The wrapper functions differ depending on the execution environment, whereas the C and C++ header files and code that are generated by the Compiler are the same for MEX-functions, stand-alone applications, and libraries.

To provide the required interface, the wrapper

- Defines persistent/global variables
- Initializes the `feval` function table for run-time `feval` support
- Performs wrapper-specific initialization and termination
- Initializes the constant pools generated by optimization

This section discusses the various wrappers that can be generated using the MATLAB Compiler.

---

**Note** When the Compiler generates a wrapper function, it must examine all of the `.m` files that will be included into the executable. If you do not include all the files, the Compiler may not define all of the global variables. Optimized code will not run at all without initialization.

---

**Generating Files**

You can use the `-t` option of the Compiler to generate source files in addition to wrapper files. For example,

```
mcc -W main -h x.m
```

examines `x.m` and all M-files referenced by `x.m`, but generates only the `x_main.c` wrapper file. However, including the `-t` option in

```
mcc -W main -h -t x.m
```

generates `x_main.c`, `x.c`, and all M-files referenced by `x.m`.
MEX-Files
The -W mex -L C options produce the MEX-file wrapper, which includes the `mexFunction` interface that is standard to all MATLAB plug-ins. For more information about the requirements of the `mex` interface, see External Interfaces/API in the MATLAB documentation.

In addition to declaring globals and initializing the `feval` function table, the MEX-file wrapper function includes interface and definition functions for all M-files not included into the set of compiled files. These functions are implemented as callbacks to MATLAB.

**Note** By default, the -x option does not include any functions that do not appear on the command line. Functions that do not appear on the command line would generate a callback to MATLAB. Specify -h if you want all functions called to be compiled into your MEX-file.

Main Files
You can generate C or C++ application wrappers that are suitable for building C or C++ stand-alone applications, respectively. These POSIX-compliant main wrappers accept strings from the POSIX shell and return a status code. They are meant to translate “command-like” M-files into POSIX main applications.

POSIX Main Wrapper
The POSIX `main()` function wrapper behaves exactly the same as the command/function duality mode of MATLAB. That is, any command of the form

```
command argument
```

can also be written in the functional form

```
command('argument')
```

If you write a function that accepts strings in MATLAB, that function will compile to a POSIX main wrapper in such a way that it behaves the same from the DOS/UNIX command line as it does from within MATLAB.
The Compiler processes the string arguments passed to the main() function and sends them into the compiled M-function as strings.

For example, consider this M-file, sample.m.

```matlab
function y = sample( varargin )
    varargin{:}
    y = 0;
```

You can compile sample.m into a POSIX main application. If you call sample from MATLAB, you get

```matlab
sample hello world
ans =
hello
ans =
world
ans =
0
```

If you compile sample.m and call it from the DOS shell, you get

```dos
C:\> sample hello world
ans =
hello
ans =
world
```

The difference between the MATLAB and DOS/UNIX environments is the handling of the return value. In MATLAB, the return value is handled by printing its value; in the DOS/UNIX shell, the return value is handled as the return status code. When you compile a function into a POSIX main application, the first return value from the function is coerced to a scalar and is returned to the POSIX shell.
Simulink S-Functions

The \texttt{-W simulink -L C} options produce a Simulink S-function wrapper. Simulink S-function wrappers conform to the Simulink C S-function conventions. The wrappers initialize

- The sizes structure
- The S-function’s sample times array
- The S-function’s states and work vectors
- The global variables and constant pool

For more information about Simulink S-function requirements, see “Writing S-Functions” in the Simulink documentation.

\textbf{Note} By default, the \texttt{-S} command does not include any functions that do not appear on the command line. Functions that do not appear on the command line would generate a callback to MATLAB. Specify \texttt{-h} if you want all functions called to be compiled into your MEX-file.

C Libraries

The intent of the C library wrapper files is to allow the inclusion of an arbitrary set of M-files into a static library or shared library. The header file contains all of the entry points for all of the compiled M functions. The export list contains the set of symbols that are exported from a C shared library.

Another benefit of creating a library is that you can compile a common set of functions once. You can then compile other M-functions that depend on them without recompiling the original functions. You can accomplish this using \texttt{mlib} files, which are automatically generated when you generate the library. For more information about \texttt{mlib} files, see “mlib Files” on page 5-26.

\textbf{Note} Even if you are not producing a shared library, you must generate a library wrapper file when including any Compiler-generated code into a larger application.
This example uses several functions from the toolbox\matlab\timefun directory (weekday, date, tic, calendar, toc) to create a library wrapper. The -W lib:libtimefun -L C options produce the files shown in this table.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>libtimefun.c</td>
<td>C wrapper file</td>
</tr>
<tr>
<td>libtimefun.h</td>
<td>C header file</td>
</tr>
<tr>
<td>libtimefun.exports</td>
<td>C export list</td>
</tr>
<tr>
<td>libtimefun.mlib</td>
<td>M-file library</td>
</tr>
</tbody>
</table>

**libtimefun.c**

The C wrapper file (libtimefun.c) contains the initialization (libtimefunInitialize) and termination (libtimefunTerminate) functions for the library. You must call libtimefunInitialize before you call any Compiler-generated code. This function initializes the state of Compiler-generated functions so that those functions can be called from C code not generated by the Compiler. You must also call libtimefunTerminate before you unload the library.

The library files in this example are produced from the command

```
mcc -W lib:libtimefun -L C weekday date tic calendar toc
```

**C Shared Library**

The MATLAB Compiler allows you to build a shared library from the files created in the previous section, “C Libraries.” To build the shared library, libtimefun.ext, in one step, use

```
mcc -B csharedlib:libtimefun weekday data tic calendar toc
```

This example uses the csharedlib bundle file

```
-t -W lib:filename -T link:lib -h libmmfile.mlib
```

The bundle file option, -B <filename>:[<a1>,<a2>,...,<an>], replaces the entire expression on the mcc command line with the contents of the specified file and it allows you to use replacement parameters. This example uses the csharedlib bundle file and replaces the expression
-B csharedlib:libtimefun

with

-t -W lib:libtimefun -T link:lib -h libmmfile.mlib

giving the new statement

mcc -t -W lib:libtimefun -T link:lib -h libmmfile.mlib weekday data tic calendar toc

The -t option tells the Compiler to generate C code from each of the listed M-files. The -T link:lib option tells the Compiler to compile and link a shared library. The -h option tells the Compiler to include any other M-functions called from those listed on the mcc command line, i.e., helper functions.

---

**Note**  You can use the -B option with a replacement expression as is at the DOS or UNIX prompt. To use -B with a replacement expression at the MATLAB prompt, you must enclose the expression that follows the -B in single quotes when there is more than one parameter passed. For example,

```plaintext
>>mcc -B csharedlib:libtimefun weekday data tic calendar toc
```
can be used as is at the MATLAB prompt because libtimefun is the only parameter being passed. If the example had two or more parameters, then the quotes would be necessary as in

```plaintext
>>mcc -B 'cexcel:component,class,1.0' weekday data tic calendar toc
```

---

**mlib Files**

Shared libraries, like libraries, let you compile a common set of functions once and then compile other M-functions that depend on them without compiling them again. You accomplish this using mlib files, which are automatically generated when you generate the shared library.

**Creating an mlib File.** When you create a library wrapper file, you also get a .mlib file with the same base name. For example,

```plaintext
mcc -W lib:libtimefun -L C -t -T link:lib -h weekday data tic calendar toc
```
creates
libtimefun.c
libtimefun.h
libtimefun.exports
libtimefun.mlib
libtimefun.ext

The last file, libtimefun.ext, is the shared library file for your platform. For example, on the PC, the shared library is

libtimefun.dll

**Using an mlib File.** This example uses two functions, tic and toc, that are in the shared library. Consider a new function, timer, defined as

```
funtion timer
  tic
    x = fft(1:1000);
  toc
```

Prior to mlib files, if you compiled timer using

```
mcc -m timer
```

both tic and toc would be recompiled due to the implicit -h option included in the -m macro. Using mlib files, you would use

```
mcc -m timer libtimefun.mlib
```

At compile time, function definitions for tic and toc are located in the libtimefun.mlib file, indicating that all future references to tic and toc should come from the mlib files's corresponding shared library. When the executable is created, it is linked against the shared library. For example, on the PC, the executable timer.exe is created and it is linked against libtimefun.dll.

An advantage of using mlib files is that the generated code is smaller because some of the code is now located in the shared library.
Note  On the `mcc` command line, you can access any `mlib` file by including the full path to the file. For example:

```
mcc -m timer /pathname/libtimefun.mlib
```

Restrictions.

- (UNIX) The first three characters of the filename must be `lib`.
- (PC and UNIX) You cannot rename the file.
- (PC and UNIX) Both the shared library and the `mlib` file must be in the same directory at compile time.
- (PC and UNIX) At run time, the path to the shared library must be on the system’s search path. For more information about setting the path on the PC, see “Shared Libraries” on page 4-22. For UNIX information, see “Locating Shared Libraries” on page 4-11. You do not need the `mlib` file present when running the executable that links to the shared library.

**C++ Libraries**

The intent of the C++ library wrapper files is to allow the inclusion of an arbitrary set of M-files into a library. The header file contains all of the entry points for all of the compiled M functions.

Note  Even if you are not producing a separate library, you must generate a library wrapper file when including any Compiler-generated code into a larger application.
This example uses several functions from the toolbox\matlab\timefun directory (weekday, date, tic, calendar, toc) to create a C++ library called libtimefun. The -W lib:libtimefun -L Cpp options produce the C++ library files shown in this table.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>libtimefun.cpp</td>
<td>C++ wrapper file</td>
</tr>
<tr>
<td>libtimefun.hpp</td>
<td>C++ header file</td>
</tr>
</tbody>
</table>

**Note** On some platforms, including Microsoft Windows NT, support for C++ shared libraries is limited and the C++ mangled function names must be exported. Refer to your vendor-supplied documentation for details on creating C++ shared libraries.

**libtimefun.cpp**

The C++ wrapper file (libtimefun.cpp) initializes the state of Compiler-generated functions so that those functions can be called from C++ code not generated by the Compiler. These files are produced from the command

```
mcc -W lib:libtimefun -L Cpp weekday date tic calendar toc
```

or using the cpplib bundle file

```
mcc -B cpplib:libtimefun weekday date tic calendar toc
```

**COM Components**

The COM wrapper file allows you to create COM components from MATLAB M-files. The Compiler options that generate the COM wrappers are

- `-W com:<component_name>[,<class_name>[,<major>.<minor>]]`
- `-W comhg:<component_name>[,<class_name>[,<major>.<minor>]]`
- `-W excel:<component_name>[,<class_name>[,<major>.<minor>]]`
- `-W excelhg:<component_name>[,<class_name>[,<major>.<minor>]]`
The COM wrapper options create a superset of the files created when producing a C or C++ library wrapper. In addition to the C or C++ library files, the COM wrapper creates the files shown in the following table.

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;component_name&gt;_idl.idl</code></td>
<td>Interface description file for COM</td>
</tr>
<tr>
<td><code>&lt;component_name&gt;_com.hpp</code></td>
<td>C++ header file for the COM class</td>
</tr>
<tr>
<td><code>&lt;component_name&gt;_com.cpp</code></td>
<td>C++ source file for the COM class</td>
</tr>
<tr>
<td><code>&lt;component_name&gt;_dll.cpp</code></td>
<td>DLL interface for the COM object</td>
</tr>
<tr>
<td><code>&lt;component_name&gt;.def</code></td>
<td>Definition file for the COM DLL</td>
</tr>
<tr>
<td><code>&lt;component_name&gt;.rc</code></td>
<td>Resource file for the COM DLL</td>
</tr>
</tbody>
</table>

If the `<class_name>` is not specified, it defaults to `<component_name>`. If the version number is not specified, it defaults to the latest version built or 1.0, if there is no previous version.

The COM wrapper option creates all the required code and files to create a single COM object that contains all of the compiler-generated interfaces. It creates a single COM class with the same name as the specified `<class_name>` and a corresponding interface class called `I<class_name>`. It uses the major and minor version numbers to control the major and minor version numbers of the COM interface that is produced.

The Compiler can generate either C or C++ code for the compiler M-files, but the created COM interface will always require C++. This is a requirement of COM and not particular to the MATLAB Compiler.

All of the extra files generated by the MATLAB Compiler that are required for producing the COM objects are added to the `mbuild` command line. The details of how `mbuild` processes the new file types (.def, .rc, and .idl) are specified in “How `mbuild` Processes the File Types” on page 5-32.

If the major and minor version numbers are specified, the Compiler replaces any existing type library with the specified new version number. If no version numbers are specified and there is an existing type library, the Compiler replaces the current version.
When calling \texttt{mbuild} to link a library, the .dll file will be \texttt{<component\_name>\_<major>\_<minor>\_dll}. This will prevent new versions from conflicting with each other. The user never uses the DLL name. It is not necessary to specify this name to the system because COM locates component DLLs using the Window’s registry.

The MATLAB Compiler uses the \texttt{-b} option to generate a Visual Basic (.bas) file that contains the Microsoft Excel Formula Function interface to the compiler-generated COM object. When imported into the workbook, this Visual Basic code allows the MATLAB function to be seen as a cell formula function.

The \texttt{-i} option causes the Compiler to include only the M-files that are specified on the command line as exported interfaces. If additional M-files are compiled as a result of being located by the \texttt{-h} option, they are not included in the exported interface that is produced by the MATLAB Compiler.

The bundle option (\texttt{-B}) provides a means to replace its expression on the \texttt{mcc} command line with the contents of the specified file. Also, it lets you include replacement parameters so that any Compiler options that accept names and version numbers will be expanded properly.

For more information on the bundle option including the available bundle files, see “\texttt{-B <filename>:\[<a1>,<a2>,...,<an>]} (Bundle of Compiler Settings)” on page 7-41.  

\textbf{Note} You can use the \texttt{-B} option with a replacement expression as is at the DOS or UNIX prompt. To use \texttt{-B} with a replacement expression at the MATLAB prompt, you must enclose the expression that follows the \texttt{-B} in single quotes when there is more than one parameter passed. For example,  

\begin{verbatim}
>>mcc -B csharedlib:libtimefun weekday data tic calendar toc
\end{verbatim}

can be used as is at the MATLAB prompt because \texttt{libtimefun} is the only parameter being passed. If the example had two or more parameters, then the quotes would be necessary as in  

\begin{verbatim}
>>mcc -B 'cexcel:component,class,1.0' weekday data tic calendar toc
\end{verbatim}
How `mbuild` Processes the File Types

The `mbuild` option, `-regsvr`, uses the mwregsvr32 program to register the resulting shared library at the end of compilation. The Compiler uses this option whenever it produces a COM wrapper file.

`<filename>.idl`. You can specify IDL source files on the `mbuild` command line. These files are compiled using the MIDL Compiler. The compiler adds any generated `.idl` files to the `mbuild` command line.

`<filename>.def`. You can specify DEF files on the `mbuild` command line to indicate the symbols exported from a given shared library. It is an error to have more than one `.def` file specified on the command line.

`<filename>.rc`. You can specify an RC file on the MATLAB Compiler command line and it is added into the DLL as required. It is an error to have more than one `.rc` file specified on the command line.

**COM Signature**

When using the MATLAB Compiler and its COM wrapper option with an M-file, the Compiler produces and registers a COM-compatible DLL.

The Compiler produces the necessary function calls in accordance with these signatures.

**M-Function Signature.**

\[ [Y1, Y2, \ldots, Varargout] = f(X1, X2, \ldots, Varargin) \]
C Signature.

```c
void mlxF(int nlhs, mxArray* plhs[],
          int nrhs, const mxArray* prhs[]);
```

```c
mxArray *mlfNF( int nargout,
              mxArray ** y1,
              mxArray **y2,
              ...
              mxArray *x1,
              mxArray *x2,
              ...
              ... );
```

COM/IDL Signature.

```c
HRESULT f([in] long nargout,
            [in,out] VARIANT* Y1,
            [in,out] VARIANT* Y2,
            ...
            [in,out] VARIANT* varargout,
            [in] VARIANT X1,
            [in] VARIANT X2,
            ...
            [in] VARIANT varargin);
```

The COM run-time performs all of the conversion between the COM types and MATLAB arrays. For details on this conversion, see the MATLAB Excel Builder or MATLAB COM Builder documentation.
Porting Generated Code to a Different Platform

The code generated by the MATLAB Compiler is portable among platforms. However, if you build an executable from `foo.m` on a PC running Windows, that same file will not run on a UNIX system.

For example, you cannot simply copy `foo.mex` (where the `mex` extension varies by platform) from a PC to a Sun system and expect the code to work, because binary formats are different on different platforms (all supported executable types are binary). However, you could copy either all of the generated C code or `foo.m` from the PC to the Sun system. Then, on the Sun platform you could use `mex` or `mcc` to produce a `foo.mex` that would work on the Sun system.

**Note**  
Stand-alone applications require that the MATLAB C/C++ Math Library be purchased for each platform where the Compiler-generated code will be executed.
Formatting Compiler-Generated Code

The formatting options allow you to control the look of the Compiler-generated C or C++ code. These options let you set the width of the generated code and the indentation levels for statements and expressions. To control code formatting, use

```
-F <option>
```

The remaining sections focus on the different choices you can use.

**Note** To improve the readability of your generated code, turn off optimizations with `-O none` or `-g`. The examples in this section have optimizations off.

Listing All Formatting Options

To view a list of all available formatting options, use

```
mcc -F list
```

Setting Page Width

Use the `-width:n` option to set the maximum width of the generated code to `n`, an integer. The default is 80 columns wide, so not selecting any page width formatting option will automatically limit your columns to 80 characters.

Setting the page width to a desired value does not guarantee that all generated lines of code will not exceed that value. There are cases where, due to indentation perhaps, a variable name may not fit within the width limit. Since variable names cannot be split, they may extend beyond the set limit. Also, to maintain the syntactic integrity of the original M source, annotations included from the M source file are not wrapped.

**Note** When using `-A line:on`, which is the default with the MATLAB add-in for Visual Studio, the page width is set as large as possible to support source-level debugging and this setting is ignored.
Default Width

Not specifying a page width formatting option uses the default of 80. Using

```
mcc -xg gasket
```

generates this code segment:

```
0 12345678901234567890123456789012345678901234567890123456789012345678901234567890
```

```c
for (mclForStart(
    &viter__, mlfScalar(1), mclVa(numPoints, "numPoints"), NULL);
    mclForNext(&viter__, &i);
) {
    /*
       * startPoint = floor((corners(theRand(i,:),)+startPoint)/2);
    */
    mclMline(21);
    mlfAssign(
        &startPoint,
        mlfFloor(
            mclMrdivide(
                mclPlus(
                    mlfIndexRef(
                        mclVv(corners, "corners"),
                        "(?,?)",
                        mlfIndexRef(
                            mclVv(theRand, "theRand"), "(?)", mclVv(i, '1')),
                            mlfCreateColonIndex()),
                            mclVv(startPoint, 'startPoint')),
                            mlfScalar(2))));
    .
    .
    .
```

Page Width = 40

This example specifies a page width of 40:

```
mcc -xg -F page-width:40 gasket
```

The segment of generated code is

```
0 12345678901234567890123456789012345678901234567890123456789012345678901234567890
```

```c
mclMline(13);
mlfAssign(
    &theImage,
    mlfZeros(
        mlfScalar(1000),
        mlfScalar(1000),
```
\[
\text{corners} = \{866, 1; 500, 866; 1000\};
\]

\[
\text{startPoint} = \{866, 1\};
\]

\[
\text{theRand} = \text{rand(numPoints, 1)};
\]

Setting Indentation Spacing

Use the \texttt{statement-indent:n} option to set the indentation of all statements to \(n\), an integer. The default is 4 spaces of indentation. To set the indentation for expressions, use \texttt{expression-indent:n}. This sets the number of spaces of indentation to \(n\), an integer, and defaults to two spaces of indentation.
Default Indentation

Not specifying indent formatting options uses the default of four spaces for statements and two spaces for expressions. For example, using

```
mcc -xg gasket
```
generates the following code segment:

```c
void mlxGasket(int nlhs, mxArray * plhs[], int nrhs, mxArray * prhs[]) {
    mxArray * mprhs[1];
    mxArray * mplhs[1];
    int i;
    if (nlhs > 1) {
        mlfError(
            mxArrayCreateString(
                "Run-time Error: File: gasket Line: 1 Column: ",
                "1 The function \"gasket\" was called with more\n                \"e than the declared number of outputs (1).\\n\\n\\"),
                NULL);
        }
    if (nrhs > 1) {
        mlfError(
            mxArrayCreateString(
                "Run-time Error: File: gasket Line: 1 Column: ",
                "1 The function \"gasket\" was called with more\n                \"e than the declared number of inputs (1).\\n\\n\\"),
                NULL);
        }
    for (i = 0; i < 1; ++i) {
        mplhs[i] = NULL;
    }
    for (i = 0; i < 1 && i < nrhs; ++i) {
        mprhs[i] = prhs[i];
    }
    for (; i < 1; ++i) {
        mprhs[i] = NULL;
    }
    mlfEnterNewContext(0, 1, mprhs[0]);
    mplhs[0] = mlxGasket(nlhs, mprhs[0]);
    mlfRestorePreviousContext(0, 1, mprhs[0]);
    plhs[0] = mplhs[0];
}
```
**Modified Indentation**

This example shows the same segment of code using a statement indentation of two and an expression indentation of one:

```shell
mcc -F statement-indent:2 -F expression-indent:1 -xg gasket
```

generates the following code segment:

```
void mlxGasket(int nlhs, mxArray * plhs[], int nrhs, mxArray * prhs[]) {
    mxArray * mprhs[1];
    mxArray * mplhs[1];
    int i;
    if (nlhs > 1) {
        mlfError(mxCreateString("Run-time Error: File: gasket Line: 1 Column: 1 The function "gaske"
                                "t" was called with more than the declared number of outputs (1)."),
                NULL);
    }
    if (nrhs > 1) {
        mlfError(mxCreateString("Run-time Error: File: gasket Line: 1 Column: 1 The function "gaske"
                                "t" was called with more than the declared number of inputs (1)."),
                NULL);
    }
    for (i = 0; i < 1; ++i) {
        mplhs[i] = NULL;
    }
    for (i = 0; i < 1 && i < nrhs; ++i) {
        mprhs[i] = prhs[i];
    }
    for (; i < 1; ++i) {
        mprhs[i] = NULL;
    }
    mlfEnterNewContext(0, 1, mprhs[0]);
    mplhs[0] = Mgasket(nlhs, mprhs[0]);
    mlfRestorePreviousContext(0, 1, mprhs[0]);
    plhs[0] = mplhs[0];
}
```
Including M-File Information in Compiler Output

The annotation options allow you to control the type of annotation in the Compiler-generated C or C++ code. These options let you include the comments and/or source code from the initial M-file(s) as well as \#line preprocessor directives. You can also use an annotation option to generate source file and line number information when you receive run-time error messages. To control code annotation, use

-A <option>

You can combine annotation options, for example, selecting both comments and \#line directives. The remaining sections focus on the different choices you can use.

Controlling Comments in Output Code

Use the annotation: type option to include your initial M-file comments and code in your generated C or C++ output. The possible values for type are

- all
- comments
- none

Not specifying any annotation type uses the default of all, which includes the complete source of the M-file (comments and code) interleaved with the generated C/C++ source.

The following sections show segments of the generated code from this simple Hello, World example:

```matlab
function hello
% This is the hello, world function written in M code
fprintf(1,'Hello, World\n');
```

**Note** To improve the readability of your generated code, turn off optimizations with -0 none or -g. The examples in this section have optimizations off.
Comments Annotation
To include only comments from the source M-file in the generated output, use

\texttt{mcc -A annotation:comments}

This code snippet shows the generated code containing only the comments
("This is the hello ...") in the middle of the routine:

\begin{verbatim}
static void Mhello(void) {
    mclMlineEnterFunction("D:\work\hello.m", "hello")
    mexLocalFunctionTable save_local_function_table_
        = mclSetCurrentLocalFunctionTable(&_local_function_table_hello);
    mxArray * ans = NULL;
    /*
     * This is the hello, world function written in M code
     */
    mclMline(3);
    mclAssignAns(
        &ans,
        mlfNFprintf(0, mlfScalar(1), mxCreateString("Hello, World\n"), NULL));
    mxArrayExitFunction();
}
\end{verbatim}

All Annotation
To include both comments and source code from the source M-file in the
generated output, use

\texttt{mcc -A annotation:all}

or do not stipulate the annotation option, thus using the default of all.

This code snippet contains both comments and source code:

\begin{verbatim}
static void Mhello(void) {
    mclMlineEnterFunction("D:\work\hello.m", "hello")
    mexLocalFunctionTable save_local_function_table_
        = mclSetCurrentLocalFunctionTable(&_local_function_table_hello);
    mxArray * ans = NULL;
    /*
     * % This is the hello, world function written in M code
     * fprintf(1,'Hello, World\n' );
     */
    mclMline(3);
    mclAssignAns(
        &ans,
        mlfNFprintf(0, mlfScalar(1), mxCreateString("Hello, World\n"), NULL));
}
\end{verbatim}
Controlling Code Generation

No Annotation

To include no source from the initial M-file in the generated output, use

```
mcc -A annotation:none
```

This code snippet shows the generated code without comments and source code:

```c
static void Mhello(void) {
    mclMlineEnterFunction("D:\work\hello.m", "hello")
    mexLocalFunctionTable save_local_function_table_ = mclSetCurrentLocalFunctionTable(&_local_function_table_hello);
    mxArray * ans = NULL;
    mclMline(3);
    mclAssignAns(&ans, mlfNFprintf(0, mlfScalar(1), mxCreateString("Hello, World\n"), NULL));
    mxDestroyArray(ans);
    mclSetCurrentLocalFunctionTable(save_local_function_table_);
    mclMlineExitFunction();
}
```

Controlling #line Directives in Output Code

#line preprocessing directives inform a C/C++ compiler that the C/C++ code was generated by another tool (MATLAB Compiler) and they identify the correspondence between the generated code and the original source code (M-file). You can use the #line directives to help debug your M-file(s). Most C language debuggers can display your M-file source code. These debuggers allow you to set breakpoints, single step, and so on at the M-file code level when you use the #line directives.

Use the line:setting option to include #line preprocessor directives in your generated C or C++ output. The possible values for setting are

- on
- off

Not specifying any line setting uses the default of off, which does not include any #line preprocessor directives in the generated C/C++ source.
Note When using the #line directive, the page-width directive is disabled in order to make the code work properly with the C debugger.

Include #line Directives
To include #line directives in your generated C or C++ code, use

```
mcc -A line:on
```

The Hello, World example produces the following code segment when this option is selected. (Note that several lines have been truncated for readability.)

```c
#include "D:\work\hello.m"                                   /* Line 1 */
static void Mhello(void) {
    #line 1 "D:\work\hello.m"                               /* Line 1 */
    mclMlineEnterFunction("D:\work\hello.m", "hello")      /* Line 1 */
    #line 1 "D:\work\hello.m"                               /* Line 1 */
    mexLocalFunctionTable save_local_function_table_ = -->
    #line 1 "D:\work\hello.m"                               /* Line 1 */
    mxArray * ans = NULL;
    /*
    * % This is the hello, world function written in M code
    * fprintf(1, 'Hello, World\n' )
    */
    #line 3 "D:\work\hello.m"                               /* Line 3 */
    mclMline(3);
    #line 3 "D:\work\hello.m"                               /* Line 3 */
    mclAssignAns(&ans, mlfNFprintf(0, mlfScalar(1), mxCreateString("Hello,-->
    #line 3 "D:\work\hello.m"                               /* Line 3 */
    mxDestroyArray(ans);
    #line 3 "D:\work\hello.m"                               /* Line 3 */
    mclSetCurrentLocalFunctionTable(save_local_function_table_);
    #line 3 "D:\work\hello.m"                               /* Line 3 */
    mclMlineExitFunction();
    #line 3 "D:\work\hello.m"                               /* Line 3 */
}
```

In this example, Line 1 points to lines in the generated C code that were produced by line 1 from the M-file, that is

```
function hello
```

Line 3 points to lines in the C code that were produced by line 3 of the M-file, or

```
fprintf(1, 'Hello, World\n' );
```
Controlling Information in Run-Time Errors

Use the debugline:setting option to include source filenames and line numbers in run-time error messages. The possible values for setting are

- on
- off

Not specifying any debugline setting uses the default of off, which does not include filenames and line numbers in the generated run-time error messages.

For example, given the M-file, tmmult.m, which in MATLAB would produce the error message Inner matrix dimensions must agree:

```matlab
function tmmult
    a = ones(2,3);
    b = ones(4,5);
    y = mmult(a,b)

function y = mmult(a,b)
    y = a*b;
```

If you create a Compiler-generated MEX-file with the command

```
mcc -x tmmult
```

and run it, your results are

```
tmmult
??? Error using ==> *
Inner matrix dimensions must agree.
```

```
Error in ==> <matlab>\toolbox\compiler\mmult.m
On line 2 ==> y = a*b;
??? Error using ==> *
Inner matrix dimensions must agree.
```

```
Error in ==> <matlab>\toolbox\compiler\tmmult.dll
```

The information about where the error occurred is not available. However, if you compile tmmult.m and use the -A debugline:on option as in

```
mcc -x -A debugline:on tmmult
```
your results are

??? Error using ==> tmmult
   Error using ==> *
   Inner matrix dimensions must agree.
   Error in File: "<matlab>\extern\examples\compiler\tmmult.m",

**Note** When using the -A debugline:on option, the lasterr function returns a string that includes the line number information. If, in your M-code, you compare against the string value of lasterr, you will get different behavior when using this option.

Since try catch end is not available in g++, do not use the -A debugline:on option on Linux when generating a C++ application.
Interfacing M-Code to C/C++ Code

The MATLAB Compiler supports calling arbitrary C/C++ functions from your M-code. You simply provide an M-function stub that determines how the code will behave in M, and then provide an implementation of the body of the function in C or C++.

C Example

Suppose you have a C function that reads data from a measurement device. In M-code, you want to simulate the device by providing a sine wave output. In production, you want to provide a function that returns the measurement obtained from the device. You have a C function called measure_from_device() that returns a double, which is the current measurement.

collect.m contains the M-code for the simulation of your application:

```plaintext
function collect

    y = zeros(1, 100); % Pre-allocate the matrix
    for i = 1:100
        y(i) = collect_one;
    end

    function y = collect_one

        persistent t;
        if (isempty(t))
            t = 0;
        end
        t = t + 0.05;
        y = sin(t);

The next step is to replace the implementation of the collect_one function with a C implementation that provides the correct value from the device each time it is requested. This is accomplished by using the %#external pragma.

The %#external pragma informs the MATLAB Compiler that the implementation version of the function (Mf) will be hand written and will not be generated from the M-code. This pragma affects only the single function in which it appears. Any M-function may contain this pragma (local, global,
private, or method). When using this pragma, the Compiler will generate an additional header file called file_external.h or file_external.hpp, where file is the name of the initial M-file containing the %#external pragma. This header file will contain the extern declaration of the function that the user must provide. This function must conform to the same interface as the Compiler-generated code.

The Compiler will still generate a .c or .cpp file from the .m file in question. The Compiler will generate the feval table, which includes the function and all of the required interface functions for the M-function, but the body of M-code from that function will be ignored. It will be replaced by the hand-written code. The Compiler will generate the interface for any functions that contain the %#external pragma into a separate file called file_external.h or file_external.hpp. The Compiler-generated C or C++ file will include this header file to get the declaration of the function being provided.

In this example, place the pragma in the collect_one local function:

```matlab
function y = zeros(1, 100); % pre-allocate the matrix
for i = 1:100
    y(i) = collect_one;
end

function y = collect_one

%#external
persistent t;
if (isempty(t))
    t = 0;
end
    t = t + 0.05;
end
    y = sin(t);

When this file is compiled, the Compiler creates the additional header file collect_external.h, which contains the interface between the Compiler-generated code and your code. In this example, it would contain

```
We recommend that you include this header file when defining the function. This function could be implemented in this C file, measure.c, using the measure_from_device() function.

```c
#include "matlab.h"
#include "collect_external.h"
#include <math.h>

extern double measure_from_device(void);

mxArray * Mcollect_collect_one(int nargout_);
{
  return( mlfScalar( measure_from_device() ));
}

double measure_from_device(void)
{
  static double t = 0.0;
  t = t + 0.05;
  return sin(t);
}
```

In general, the Compiler will use the same interface for this function as it would generate. To generate the C code and header file, use

```
mcc -mc collect.m
```

By examining the Compiler-generated C code, you should easily be able to determine how to implement this interface. To compile collect.m to a MEX-file, use

```
mcc -x collect.m measure.c
```

**Using Pragmas**

**Using feval**

In stand-alone C and C++ modes, the pragma

```
  %#function <function_name-list>
```

informs the MATLAB Compiler that the specified function(s) will be called through an feval call or through a MATLAB function that accepts a function to feval as an argument or contains an eval string or Handle Graphics.
callback that references the specified function. Without this pragma, the -h option will not be able to locate and compile all M-files used in your application.

If you are using the %#function pragma to define functions that are not available in M-code, you must write a dummy M-function that identifies the number of input and output parameters to the M-file function with the same name used on the %#function line. For example:

%#function myfunctionwritteninc

This implies that myfunctionwritteninc is an M-function that will be called using feval. The Compiler will look up this function to determine the correct number of input and output variables.

**Compiling MEX-Files**

If the Compiler finds both a function M-file and a .mex file in the same directory, it will assume that the .mex file is the compiled version of the M-file. In those cases, if the M-file version is not desired, use the %#mex pragma to force the Compiler to use the MEX-file. For example:

```matlab
function y = gamma(x)
    %#mex
    error('gamma MEX-file is missing');
```
Optimizing Performance

The MATLAB Compiler can perform various optimizations on your M-file source code that can make the performance of the generated C/C++ code much faster than the performance of the M-code in the MATLAB interpreter.

MATLAB Compiler 3.0 provides a series of optimizations that can help speed up your compiled code. This chapter describes the optimization options.

The only times you would choose not to optimize are if you are debugging your code or you want to maintain the readability of your code.

- **Optimization Bundles (p. 6-2)**: Bundles that allow you to select the most common optimization options
- **Optimizing Arrays (p. 6-4)**: Improving the performance of code that manipulates scalar arrays
- **Optimizing Loops (p. 6-6)**: Improving the performance of simple one- and two-dimensional array index expressions
- **Optimizing Conditionals (p. 6-9)**: Reducing the MATLAB conditional operators to scalar C conditional operators
- **Optimizing MATLAB Arrays (p. 6-10)**: Accelerates scalar math operations
Optimization Bundles

All optimizations are controlled separately, and you can enable or disable any of the optimizations. To simplify the process, you can use the provided bundles of Compiler settings that allow you to select the most common optimization options. For more information on bundles, see “-B <filename>:[<a1>,<a2>,...,<an>] (Bundle of Compiler Settings)” on page 7-41.

Turn On All Optimizations
To turn on all optimizations, use

```
-0 all
```

This bundle is stored in

```
<matlab>/toolbox/compiler/bundles/opt_bundle_all
```

By default, all optimizations, except speculate, are on unless you specifically disable them or use the -g option for debugging. The -g option disables all optimizations.

Turn Off All Optimizations
To turn off all optimizations, use

```
-0 none
```

This bundle is stored in

```
<matlab>/toolbox/compiler/bundles/opt_bundle_none
```

This optimization setting is used whenever you use -g for debugging.

Turn On Individual Optimizations
You can enable or disable each individual optimization. To enable/disable an optimization, use

```
-0 <optimization option>:[on|off]
```

where <optimization option> is

- array_indexing
- fold_mxarrays
- fold_non_scalar_mxarrays
- fold_scalar_mxarrays
- optimize_conditionals
• optimize_integer_for_loops
• percolate_simple_types
• speculate

List All Optimizations
To list all available optimizations, use

  -O list
Optimizing Arrays

**Scalar Arrays**
(fold_scalar_mxarrays) When this optimization is enabled, all constant, scalar-valued array operations are *folded* at compile time and are stored in a constant pool that is created once at program initialization time. Folding reduces the number of computations that are performed at run-time, thus improving run-time performance.

Scalar folding can dramatically improve the performance of code that is manipulating scalar arrays, but it makes the code less readable. For example:

```matlab
function y = foo(x)
y = 2*pi*x;
```

If you compile this with the `-O none` option, you get

```matlab
... mlfAssign(&y, mclMtimes(mlfScalar(6.283185307179586), mclVa(x, "x"))); ...
```

Compiling with `-O none -O fold_scalar_mxarrays: on`, gives

```matlab
... mlfAssign(&y, mclMtimes(_mxarray0_, mclVa(x, "x"))); ...
```

In the optimized case, this code uses `_mxarray0_`, which is initialized at program start-up to hold the correct value. All constants with the same value use the same `mxArray` variable in the constant pool.

**Nonscalar Arrays**
(fold_non_scalar_mxarrays) This optimization is very similar to `fold_scalar_mxarrays`. It folds nonscalar `mxArray` values into compile-time arrays that are initialized at program start-up. This can have a large performance impact if you are constructing arrays that use `[]` or `{}` within a loop. This optimization makes the code less readable. For example:

```matlab
function y = test
y = [ 1 0; 0 1] * [ pi pi/2; -pi -pi/2 ];
```
If you compile this with the `-O none` option, you get

```c
...  
mlfAssign(  
    &y,  
    mclMtimes(  
        mlfDoubleMatrix(2, 2, _array0_, (double *)NULL),  
        mlfDoubleMatrix(2, 2, _array1_, (double *)NULL)));
...  
```

Compiling with `-O none -O fold_non_scalar_mxarrays: on` gives

```c
...  
mlfAssign(&y, _mxarray4_);  
...  
```

** Scalars**

(fold_mxarrays) This option is equivalent to using both `fold_scalar_mxarrays` and `fold_non_scalar_mxarrays`. It is included for compatibility with P-code generation.
Optimizing Loops

Simple Indexing
(array_indexing) This optimization improves the performance of simple one- and two-dimensional array index expressions. Without this optimization, all array indexing uses the fully general array indexing function, which is not optimized for one- and two-dimensional indexing. With this optimization enabled, indexing uses faster routines that are optimized for simple indexing.

For example:

```c
function y = test(x,i1,i2);
y = x(i1,i2);
```

If you compile this with the -O none option, you get

```c
...
mlfAssign(
    &y,
    mlfIndexRef(mclVa(x, "x"), "(?,?)", mclVa(i1, "i1"),
     mclVa(i2, "i2")));
...
```

Compiling with -O none -O array_indexing:on gives

```c
...
mlfAssign(
    &y, mclArrayRef2(mclVa(x, "x"), mclVa(i1, "i1"),
     mclVa(i2,"i2"));
...
```

The mclArrayRef2 function is optimized for two-dimensional indexing. mclArrayRef1 is used for one-dimensional indexing.

Loop Simplification
(optimize_integer_for_loops) This optimization detects when a loop starts and increments with integers. It replaces the loop with a much simpler loop that uses C integer variables instead of array-valued variables. The performance improvements with this optimization can be dramatic.
This optimization causes the variable names in the resulting C program to differ from those in the M-file. Therefore, we recommend that you do not use this option when debugging.

For example:

```matlab
function test(x)
    for i = 1:length(x)-1
        x(i) = x(i) + x(i+1)
    end
```

If you compile this with the `-O none` option, you get

```c
{
    mclForLoopIterator viter__;
    for (mclForStart(
        &viter__,
        mlfScalar(1),
        mclMinus(mlfLength(mclVa(x, "x")),
        mlfScalar(1)), NULL);
    mclForNext(&viter__, &i);
    ) {
        ...
    }
    mclDestroyForLoopIterator(viter__);
}
```

Compiling with `-O none -O optimize_integer_for_loops:on` gives

```c
{
    int v_ = mclForIntStart(1);
    int e_ = mclLengthInt(mclVa(x, "x")) - 1;
    if (v_ > e_) {
        mlfAssign(&i, _mxarray0_);
    } else {
        ...
    }
```
for (; ; ) {
    ...
    if (v_ == e_) {
        break;
    }
    ++v_;
}
mlfAssign(&i, mlfScalar(v_));
Optimizing Conditionals

(optimize_conditionals) This optimization reduces the MATLAB conditional operators to scalar C conditional operators when both operands are known to be integer scalars. The Compiler "knows" that nargin, nargout, and for-loop control variables (when using the above optimization) are integer scalars. For example:

```matlab
function test(a,b,c,d)
    if (nargin < 4)
        d = 0.0;
    end
```

If you compile this with the `-0 none` option, you get

```matlab
... if (mlfTobool(mclLt(mlfScalar(nargin_), mlfScalar(4)))) {
...
```

Compiling with `-0 none -O optimize_conditionals:on` gives

```matlab
... if (nargin_ < 4) {
...
```
Optimizing MATLAB Arrays

**Scalars**

(percolate_simple_types) This optimization reduces the strength of operations on simple types (scalars) by reducing operations to scalar double operations whenever possible. For example, if your code uses $\sin(v)$ and $v$ is known to be double and scalar, this optimization uses the scalar double $\sin$ function. This optimization is always on when compiling to C/C++ and cannot be disabled. It is provided for compatibility with P-code generation.

**Scalar Doubles**

(speculate) This optimization is similar to the technology used by MATLAB to accelerate scalar double math operations. It makes educated guesses about the type of MATLAB arrays, and optimizes the code accordingly. This optimization can have dramatic impact on scalar double MATLAB code and more modest impact on small array operations. This optimization is off by default.

</tr>
</tbody>
</table>
### Purpose
feval pragma

### Syntax
```
%#function <function_name-list>
```

### Description
This pragma informs the MATLAB Compiler that the specified function(s) will be called through an `feval`, `eval`, or Handle Graphics callback. You need to specify this pragma only to assist the Compiler in locating and automatically compiling the set of functions when using the `-h` option.

If you are using the `%#function` pragma to define functions that are not available in M-code, you should use the `%#external` pragma to define the function. For example:

```
%#function myfunctionwritteninc
```

This implies that `myfunctionwritteninc` is an M-function that will be called using `feval`. The Compiler will look up this function to determine the correct number of input and output variables. Therefore, you need to provide a dummy M-function that contains a function line and a `%#external` pragma, such as

```
function y = myfunctionwritteninc( a, b, c );
 %#external
```

The `function` statement indicates that the function takes three inputs (a, b, c) and returns a single output variable (y). No additional lines need to be present in the M-file.
Purpose  mex pragma
Syntax  %#mex
Description  This pragma informs the MATLAB Compiler to select the MEX-file over an existing M-file.

If you are using the %#function pragma to define functions that are not available in M-code, you should use the %#external pragma to define the function. For example:

```matlab
function y = gamma(x)
    %#mex
    error('gamma MEX-file is missing');
```
Purpose

Assert variable is a MATLAB character string

Syntax

mbchar(x)

Description

The statement

mbchar(x)

causes the MATLAB Compiler to impute that x is a char matrix. At run-time, if mbchar determines that x does not hold a char matrix, mbchar issues an error message and halts execution of the MEX-file.

mbchar tells the MATLAB interpreter to check whether x holds a char matrix. If x does not, mbchar issues an error message and halts execution of the M-file. The MATLAB interpreter does not use mbchar to impute x.

Note that mbchar only tests x at the point in an M-file or MEX-file where an mbchar call appears. In other words, an mbchar call tests the value of x only once. If x becomes something other than a char matrix after the mbchar test, mbchar cannot issue an error message.

A char matrix is any scalar, vector, or matrix that contains only the char data type.

Example

This code in MATLAB causes mbchar to generate an error message because n does not contain a char matrix:

n = 17;
mbchar(n);
??? Error using ==> mbchar
Argument to mbchar must be of class 'char'.

See Also

mbcharvector, mbcharscalar, mbreal, mbscalar, mbvector, mbintscalar, mbintvector, mcc
Purpose
Assert variable is a character scalar

Syntax
mbcharscalar(x)

Description
The statement
mbcharscalar(x)
causes the MATLAB Compiler to impute that x is a character scalar, i.e., an unsigned short variable. At run-time, if mbcharscalar determines that x holds a value other than a character scalar, mbcharscalar issues an error message and halts execution of the MEX-file.

mbcharscalar tells the MATLAB interpreter to check whether x holds a character scalar value. If x does not, mbcharscalar issues an error message and halts execution of the M-file. The MATLAB interpreter does not use mbcharscalar to impute x.

Note that mbcharscalar only tests x at the point in an M-file or MEX-file where an mbcharscalar call appears. In other words, an mbcharscalar call tests the value of x only once. If x becomes a vector after the mbcharscalar test, mbcharscalar cannot issue an error message.

mbcharscalar defines a character scalar as any value that meets the criteria of both mbchar and mbscalar.

Example
This code in MATLAB generates an error message:

```
n = ['hello' 'world'];
mbcharscalar(n)
??? Error using ==> mbscalar
Argument of mbscalar must be scalar.
```

See Also
mbchar, mbcharvector, mbreal, mbscalar, mbvector, mbintscalar, mbintvector, mcc
**mbcharvector**

**Purpose**
Assert variable is a character vector, i.e., a MATLAB string

**Syntax**
`mbcharvector(x)`

**Description**
The statement

```
mbcharvector(x)
```

causes the MATLAB Compiler to impute that `x` is a `char` vector. At run-time, if `mbcharvector` determines that `x` holds a value other than a `char` vector, `mbcharvector` issues an error message and halts execution of the MEX-file.

`mbcharvector` tells the MATLAB interpreter to check whether `x` holds a `char` vector value. If `x` does not, `mbcharvector` issues an error message and halts execution of the M-file. The MATLAB interpreter does not use `mbcharvector` to impute `x`.

Note that `mbcharvector` only tests `x` at the point in an M-file or MEX-file where an `mbcharvector` call appears. In other words, an `mbcharvector` call tests the value of `x` only once. If `x` becomes something other than a `char` vector after the `mbcharvector` test, `mbcharvector` cannot issue an error message.

`mbcharvector` defines a `char` vector as any value that meets the criteria of both `mbchar` and `mbvector`. Note that `mbcharvector` considers `char` scalars as `char` vectors as well.

**Example**
This code in MATLAB causes `mbcharvector` to generate an error message because, although `n` is a vector, `n` contains one value that is not a `char`:

```
n = [1:5];
mbcharvector(n)
??? Error using ==> mbchar
    Argument to mbchar must be of class 'char'.
```

**See Also**
`mbchar`, `mbcharscalar`, `mbscalar`, `mbreal`, `mbvector`, `mbintvector`, `mcc`
**Purpose**

Assert variable is integer

**Syntax**

mbint(n)

**Description**

The statement

```
mbint(x)
```

causes the MATLAB Compiler to impute that \(x\) is an integer. At run-time, if \(\text{mbint}\) determines that \(x\) holds a noninteger value, the generated code issues an error message and halts execution of the MEX-file.

\(\text{mbint}\) tells the MATLAB interpreter to check whether \(x\) holds an integer value. If \(x\) does not, \(\text{mbint}\) issues an error message and halts execution of the M-file. The MATLAB interpreter does not use \(\text{mbint}\) to impute a data type to \(x\).

Note that \(\text{mbint}\) only tests \(x\) at the point in an M-file or MEX-file where an \(\text{mbint}\) call appears. In other words, an \(\text{mbint}\) call tests the value of \(x\) only once. If \(x\) becomes a noninteger after the \(\text{mbint}\) test, \(\text{mbint}\) cannot issue an error message.

\(\text{mbint}\) defines an integer as any scalar, vector, or matrix that contains only integer or string values. For example, \(\text{mbint}\) considers \(n\) to be an integer because all elements in \(n\) are integers.

\[
    n = [5 7 9];
\]

If even one element of \(n\) contains a fractional component, for example,

\[
    n = [5 7 9.2];
\]

then \(\text{mbint}\) assumes that \(n\) is not an integer.

\(\text{mbint}\) considers all strings to be integers.

If \(n\) is a complex number, then \(\text{mbint}\) considers \(n\) to be an integer if both its real and imaginary parts are integers. For example, \(\text{mbint}\) considers the value of \(n\) an integer.

\[
    n = 4 + 7i
\]

\(\text{mbint}\) does not consider the value of \(x\) an integer because one of the parts (the imaginary) has a fractional component:
\[ x = 4 + 7.5i; \]

**Example**  
This code in MATLAB causes `mbint` to generate an error message because \( n \) does not hold an integer value:

\[
\begin{align*}
    n &= 17.4; \\
    \text{mbint}(n); \\
    ??? \text{ Error using } ==> \text{ mbint} \\
    \text{Argument to mbint must be integer.}
\end{align*}
\]

**See Also**  
`mbintscalar`, `mbintvector`, `mcc`
Purpose
Assert variable is integer scalar

Syntax
mbintscalar(n)

Description
The statement
mbintscalar(x)
causes the MATLAB Compiler to impute that x is an integer scalar. At
run-time, if mbintscalar determines that x holds a value other than an integer
scalar, mbintscalar issues an error message and halts execution of the
MEX-file.

mbintscalar tells the MATLAB interpreter to check whether x holds an
integer scalar value. If x does not, mbintscalar issues an error message and
halts execution of the M-file. The MATLAB interpreter does not use
mbintscalar to impute x.

Note that mbintscalar only tests x at the point in an M-file or MEX-file where
an mbintscalar call appears. In other words, an mbintscalar call tests the
value of x only once. If x becomes a vector after the mbintscalar test,
mbintscalar cannot issue an error message.

mbintscalar defines an integer scalar as any value that meets the criteria of
both mbint and mbscalar.

Example
This code in MATLAB causes mbintscalar to generate an error message
because, although n is a scalar, n does not hold an integer value:

n = 4.2;
mbintscalar(n)
??? Error using ==> mbint
Argument to mbint must be integer.

See Also
mbint, mbscalar, mcc
**mbintvector**

**Purpose**  
Assert variable is integer vector

**Syntax**  
`mbintvector(n)`

**Description**  
The statement

```matlab
mbintvector(x)
```

causes the MATLAB Compiler to impute that `x` is an integer vector. At run-time, if `mbintvector` determines that `x` holds a value other than an integer vector, `mbintvector` issues an error message and halts execution of the MEX-file.

`mbintvector` tells the MATLAB interpreter to check whether `x` holds an integer vector value. If `x` does not, `mbintvector` issues an error message and halts execution of the M-file. The MATLAB interpreter does not use `mbintvector` to impute `x`.

Note that `mbintvector` only tests `x` at the point in an M-file or MEX-file where an `mbintvector` call appears. In other words, an `mbintvector` call tests the value of `x` only once. If `x` becomes a two-dimensional matrix after the `mbintvector` test, `mbintvector` cannot issue an error message.

`mbintvector` defines an integer vector as any value that meets the criteria of both `mbint` and `mbvector`. Note that `mbintvector` considers integer scalars to be integer vectors as well.

**Example**  
This code in MATLAB causes `mbintvector` to generate an error message because, although all the values of `n` are integers, `n` is a matrix rather than a vector:

```matlab
n = magic(2)
n =
    1     3
    4     2
mbintvector(n)
??? Error using ==> mbvector
    Argument to mbvector must be a vector.
```

**See Also**  
`mbint`, `mbvector`, `mbintscalar`, `mcc`
Purpose

Assert variable is real

Syntax

mbreal(n)

Description

The statement

mbreal(x)

causes the MATLAB Compiler to impute that x is real (not complex). At
run-time, if mbreal determines that x holds a complex value, mbreal issues an
error message and halts execution of the MEX-file.

mbreal tells the MATLAB interpreter to check whether x holds a real value. If
x does not, mbreal issues an error message and halts execution of the M-file.
The MATLAB interpreter does not use mbreal to impute x.

Note that mbreal only tests x at the point in an M-file or MEX-file where an
mbreal call appears. In other words, an mbreal call tests the value of x only
once. If x becomes complex after the mbreal test, mbreal cannot issue an error
message.

A real value is any scalar, vector, or matrix that contains no imaginary
components.

Example

This code in MATLAB causes mbreal to generate an error message because n
contains an imaginary component:

```
n = 17 + 5i;
mbreal(n);
??? Error using ==> mbreal
Argument to mbreal must be real.
```

mbreal scalar, mbreal vector, mcc
**mbrealscalar**

**Purpose**
Assert variable is real scalar

**Syntax**

```
mbrealscalar(n)
```

**Description**
The statement

```
mbrealscalar(x)
```

causes the MATLAB Compiler to impute that `x` is a real scalar. At run-time, if `mbrealscalar` determines that `x` holds a value other than a real scalar, `mbrealscalar` issues an error message and halts execution of the MEX-file.

`mbrealscalar` tells the MATLAB interpreter to check whether `x` holds a real scalar value. If `x` does not, `mbrealscalar` issues an error message and halts execution of the M-file. The MATLAB interpreter does not use `mbrealscalar` to impute `x`.

Note that `mbrealscalar` only tests `x` at the point in an M-file or MEX-file where an `mbrealscalar` call appears. In other words, an `mbrealscalar` call tests the value of `x` only once. If `x` becomes a vector after the `mbrealscalar` test, `mbrealscalar` cannot issue an error message.

`mbrealscalar` defines a real scalar as any value that meets the criteria of both `mbreal` and `mbscalar`.

**Example**
This code in MATLAB causes `mbrealscalar` to generate an error message because, although `n` contains only real numbers, `n` is not a scalar:

```
    n = [17.2 15.3];
    mbrealscalar(n)
    ??? Error using ==> mbscalar
    Argument of mbscalar must be scalar.
```

Purpose  Assert variable is a real vector
Syntax  \texttt{mbrealvector(n)}
Description  The statement
\begin{verbatim}
    mbrealvector(x)
\end{verbatim}
causes the MATLAB Compiler to impute that \( x \) is a real vector. At run-time, if \texttt{mbrealvector} determines that \( x \) holds a value other than a real vector, \texttt{mbrealvector} issues an error message and halts execution of the MEX-file.
\texttt{mbrealvector} tells the MATLAB interpreter to check whether \( x \) holds a real vector value. If \( x \) does not, \texttt{mbrealvector} issues an error message and halts execution of the M-file. The MATLAB interpreter does not use \texttt{mbrealvector} to impute \( x \).
Note that \texttt{mbrealvector} only tests \( x \) at the point in an M-file or MEX-file where an \texttt{mbrealvector} call appears. In other words, an \texttt{mbrealvector} call tests the value of \( x \) only once. If \( x \) becomes complex after the \texttt{mbrealvector} test, \texttt{mbrealvector} cannot issue an error message.
\texttt{mbrealvector} defines a real vector as any value that meets the criteria of both \texttt{mbreal} and \texttt{mbvector}. Note that \texttt{mbrealvector} considers real scalars to be real vectors as well.
Example  This code in MATLAB causes \texttt{mbrealvector} to generate an error message because, although \( n \) is a vector, \( n \) contains one imaginary number:
\begin{verbatim}
    n = [5 2+3i];
    mbrealvector(n)
    ??? Error using ==> mbreal
        Argument to mbreal must be real.
\end{verbatim}
See Also  \texttt{mbreal, mbrealscalar, mbvector, mcc}
**mbscalar**

**Purpose**  
Assert variable is scalar

**Syntax**  
`mbscalar(n)`

**Description**  
The statement  
`mbscalar(x)`  
causes the MATLAB Compiler to impute that `x` is a scalar. At run-time, if  
`mbscalar` determines that `x` holds a nonscalar value, `mbscalar` issues an error  
message and halts execution of the MEX-file.

`mbscalar` tells the MATLAB interpreter to check whether `x` holds a scalar  
value. If `x` does not, `mbscalar` issues an error message and halts execution of  
the M-file. The MATLAB interpreter does not use `mbscalar` to impute `x`.

Note that `mbscalar` only tests `x` at the point in an M-file or MEX-file where an  
mbscalar call appears. In other words, an `mbscalar` call tests the value of `x` only  
once. If `x` becomes nonscalar after the `mbscalar` test, `mbscalar` cannot issue an  
error message.

`mbscalar` defines a scalar as a matrix whose dimensions are 1-by-1.

**Example**  
This code in MATLAB causes `mbscalar` to generate an error message because  
`n` does not hold a scalar:

```matlab  
n = [1 2 3];  
mbscalar(n);  
??? Error using ==> mbscalar  
Argument of mbscalar must be scalar.  
```

**See Also**  
`mbint`, `mbintscalar`, `mbintvector`, `mbreal`, `mbrealscalar`, `mbrealvector`,  
`mbvector`, `mcc`
**mbvector**

**Purpose**  
Assert variable is vector

**Syntax**  
`mbvector(n)`

**Description**  
The statement

```
mbvector(x)
```

causes the MATLAB Compiler to impute that `x` is a vector. At run-time, if `mbvector` determines that `x` holds a nonvector value, `mbvector` issues an error message and halts execution of the MEX-file.

`mbvector` causes the MATLAB interpreter to check whether `x` holds a vector value. If `x` does not, `mbvector` issues an error message and halts execution of the M-file. The MATLAB interpreter does not use `mbvector` to impute `x`.

Note that `mbvector` only tests `x` at the point in an M-file or MEX-file where an `mbvector` call appears. In other words, an `mbvector` call tests the value of `x` only once. If `x` becomes a nonvector after the `mbvector` test, `mbvector` cannot issue an error message.

`mbvector` defines a vector as any matrix whose dimensions are 1-by-`n` or `n`-by-1. All scalars are also vectors (though most vectors are not scalars).

**Example**  
This code in MATLAB causes `mbvector` to generate an error message because the dimensions of `n` are 2-by-2:

```matlab
n = magic(2)
n =
1 3
4 2
mbvector(n)
??? Error using ==> mbvector
Argument to mbvector must be a vector.
```

**mbuild**

**Purpose**  
Compile and link source files that call functions in the MATLAB C/C++ Math Library or MATLAB C/C++ Graphics Library into a stand-alone executable or shared library.

**Syntax**  
`mbuild [option1 ... optionN] sourcefile1 [... sourcefileN]  
[objectfile1 ... objectfileN] [libraryfile1 ... libraryfileN]  
[exportfile1 ... exportfileN]`

**Note**  
Supported types of source files are: .c, .cpp, .idl, .rc. To specify IDL source files to be compiled with the MIDL Compiler, add `<filename>.idl` to the `mbuild` command line; to specify a DEF file, add `<filename>.def` to the command line; to specify an RC file, add `<filename>.rc` to the command line. Source files that are not one of the supported types are passed to the linker.

**Description**  
`mbuild` is a script that supports various options that allow you to customize the building and linking of your code. Table 7-1, `mbuild` Options, lists the `mbuild` options. If no platform is listed, the option is available on both UNIX and Microsoft Windows.

**Table 7-1: mbuild Options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-&lt;arch&gt;</td>
<td>(UNIX) Assume local host has architecture <code>&lt;arch&gt;</code>. Possible values for <code>&lt;arch&gt;</code> include sol2, hpux, hp700, alpha, ibm_rs, sgi, and glnx86.</td>
</tr>
<tr>
<td>@&lt;response_file&gt;</td>
<td>(Windows) Replace @&lt;response_file&gt; on the <code>mbuild</code> command line with the contents of the text file, response_file.</td>
</tr>
<tr>
<td>-c</td>
<td>Compile only. Do not link. Creates an object file but not an executable.</td>
</tr>
<tr>
<td>-D&lt;name&gt;</td>
<td>Define a symbol name to the C/C++ preprocessor. Equivalent to a <code>#define &lt;name&gt;</code> directive in the source.</td>
</tr>
</tbody>
</table>
### Table 7-1: mbuild Options (Continued)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-D&lt;name&gt;#&lt;value&gt;</code></td>
<td>Define a symbol name and value to the C/C++ preprocessor. Equivalent to a <code>#define &lt;name&gt; &lt;value&gt;</code> directive in the source.</td>
</tr>
<tr>
<td><code>-D&lt;name&gt;=&lt;value&gt;</code></td>
<td>(UNIX) Define a symbol name and value to the C preprocessor. Equivalent to a <code>#define &lt;name&gt; &lt;value&gt;</code> directive in the source.</td>
</tr>
<tr>
<td><code>-f &lt;&lt;optionsfile&gt;&gt;</code></td>
<td>Specify location and name of options file to use. Overrides the <code>mbuild</code> default options file search mechanism.</td>
</tr>
<tr>
<td><code>-g</code></td>
<td>Create a debuggable executable. If this option is specified, <code>mbuild</code> appends the value of options file variables ending in <code>DEBUGFLAGS</code> with their corresponding base variable. This option also disables the <code>mbuild</code> default behavior of optimizing built object code.</td>
</tr>
<tr>
<td><code>-h[elp]</code></td>
<td>Help; prints a description of <code>mbuild</code> and the list of options.</td>
</tr>
<tr>
<td><code>-I&lt;pathname&gt;</code></td>
<td>Add <code>&lt;pathname&gt;</code> to the list of directories to search for <code>#include</code> files.</td>
</tr>
<tr>
<td><code>-inline</code></td>
<td>Inline matrix accessor functions (<code>mx*</code>). The generated executable may not be compatible with future versions of the MATLAB C/C++ Math Library or MATLAB C/C++ Graphics Library.</td>
</tr>
<tr>
<td><code>-l&lt;name&gt;</code></td>
<td>(UNIX) Link with object library <code>lib&lt;name&gt;</code>.</td>
</tr>
<tr>
<td><code>-L&lt;directory&gt;</code></td>
<td>(UNIX) Add <code>&lt;directory&gt;</code> to the list of directories containing object-library routines.</td>
</tr>
</tbody>
</table>
Specify compiler language. `<language>` can be c or cpp. By default, `mbuild` determines which compiler (C or C++) to use by inspection of the source file's extension. This option overrides that mechanism. This option is necessary when you use an unsupported file extension, or when you pass in all `.o` files and libraries.

No execute mode. Print out any commands that `mbuild` would execute, but do not actually execute any of them.

Do not link against the MATLAB C/C++ Graphics Library (Handle Graphics).

Optimize the object code by including the optimization flags listed in the options file. If this option is specified, `mbuild` appends the value of options file variables ending in `OPTIMFLAGS` with their corresponding base variable. Note that optimizations are enabled by default, are disabled by the `-g` option, but are reenabled by `-O`.

Place any generated object, resource, or executable files in the directory `<dirname>`. Do not combine this option with `-output` if the `-output` option gives a full pathname.

Create an executable named `<resultname>`. An appropriate executable extension is automatically appended. Overrides the `mbuild` default executable naming mechanism.
Table 7-1: mbuild Options (Continued)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-regsvr</td>
<td>(Windows) Use the regsvr32 program to register the resulting shared library at the end of compilation. The Compiler uses this option whenever it produces a COM wrapper file.</td>
</tr>
<tr>
<td>-setup</td>
<td>Interactively specify the compiler options file to use as default for future invocations of mbuild by placing it in <code>&lt;UserProfile&gt;\Application Data\MathWorks\MATLAB\R13</code> (Windows) or <code>$HOME/.matlab/R13</code> (UNIX). When this option is specified, no other command line input is accepted.</td>
</tr>
<tr>
<td>-U&lt;name&gt;</td>
<td>Remove any initial definition of the C preprocessor symbol <code>&lt;name&gt;</code>. (Inverse of the -D option.)</td>
</tr>
<tr>
<td>-v</td>
<td>Verbose; Print the values for important internal variables after the options file is processed and all command line arguments are considered. Prints each compile step and final link step fully evaluated to see which options and files were used. Very useful for debugging.</td>
</tr>
</tbody>
</table>
### Table 7-1: `mbuild` Options (Continued)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;name&gt;=&lt;value&gt;</code></td>
<td>(UNIX) Override an options file variable for variable <em>&lt;name&gt;</em>. If <em>&lt;value&gt;</em> contains spaces, enclose it in single quotes, e.g., <code>CFLAGS='opt1 opt2'</code>. The definition, <code>&lt;def&gt;</code>, can reference other variables defined in the options file. To reference a variable in the options file, prepend the variable name with a $, e.g., <code>CFLAGS='$CFLAGS opt2'</code>.</td>
</tr>
<tr>
<td><code>&lt;name&gt;#&lt;value&gt;</code></td>
<td>Override an options file variable for variable <em>&lt;name&gt;</em>. If <code>&lt;def&gt;</code> contains spaces, enclose it in single quotes, e.g., <code>CFLAGS='opt1 opt2'</code>. The definition, <code>&lt;def&gt;</code>, can reference other variables defined in the options file. To reference a variable in the options file, prepend the variable name with a $, e.g., <code>CFLAGS='$CFLAGS opt2'</code>.</td>
</tr>
</tbody>
</table>

**Note** Some of these options (`-f`, `-g`, and `-v`) are available on the `mcc` command line and are passed along to `mbuild`. Others can be passed along using the `-M` option to `mcc`. For details on the `-M` option, see the `mcc` reference page.
Purpose

Invoke MATLAB Compiler

Syntax

mcc [-options] mfile1  [mfile2 ... mfileN]
[C/C++file1 ... C/C++fileN]

Description

mcc is the MATLAB command that invokes the MATLAB Compiler. You can issue the mcc command either from the MATLAB command prompt (MATLAB mode) or the DOS or UNIX command line (stand-alone mode).

Command Line Syntax

You may specify one or more MATLAB Compiler option flags to mcc. Most option flags have a one-letter name. You can list options separately on the command line, for example:

mcc -m -g myfun

You can group options that do not take arguments by preceding the list of option flags with a single dash (-), for example:

mcc -mg myfun

Options that take arguments cannot be combined unless you place the option with its arguments last in the list. For example, these formats are valid:

mcc -m -A full myfun % Options listed separately
mcc -mA full myfun % Options combined, A option last

This format is not valid:

mcc -Am full myfun % Options combined, A option not last

In cases where you have more than one option that takes arguments, you can only include one of those options in a combined list and that option must be last. You can place multiple combined lists on the mcc command line.

If you include any C or C++ filenames on the mcc command line, the files are passed directly to mex or mbuild, along with any Compiler-generated C or C++ files.

Using Macros to Simplify Compilation

The MATLAB Compiler, through its exhaustive set of options, gives you access to the tools you need to do your job. If you want a simplified approach to
compilation, you can use one simple option, i.e., `macro`, that allows you to quickly accomplish basic compilation tasks. If you want to take advantage of the power of the Compiler, you can do whatever you desire to do by choosing various Compiler options.

Table 7-2, Macro Options, shows the relationship between the macro approach to accomplish a standard compilation and the multioption alternative.

**Table 7-2: Macro Options**

<table>
<thead>
<tr>
<th>Macro Option</th>
<th>Bundle File</th>
<th>Creates</th>
<th>Option Equivalence</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-m</code></td>
<td><code>macro_option_m</code></td>
<td>Stand-alone C application</td>
<td><code>-t -W main -L C -T link:exe -h libmmfile.mlib</code></td>
</tr>
<tr>
<td><code>-p</code></td>
<td><code>macro_option_p</code></td>
<td>Stand-alone C++ application</td>
<td><code>-t -W main -L Cpp -T link:exe -h libmmfile.mlib</code></td>
</tr>
<tr>
<td><code>-x</code></td>
<td><code>macro_option_x</code></td>
<td>MEX-function</td>
<td><code>-t -W mex -L C -T link:mexlibrary libmatlbmx.mlib</code></td>
</tr>
<tr>
<td><code>-S</code></td>
<td><code>macro_option_S</code></td>
<td>Simulink S-function</td>
<td><code>-t -W simulink -L C -T link:mex libmatlbmx.mlib</code></td>
</tr>
<tr>
<td><code>-g</code></td>
<td><code>macro_option_g</code></td>
<td>Enable debug</td>
<td><code>-G -A debugline:on -O none</code></td>
</tr>
</tbody>
</table>

**Understanding a Macro Option.** The `-m` option tells the Compiler to produce a stand-alone C application. The `-m` macro is equivalent to the series of options

```
-t -W main -L C -T link:exe -h libmmfile.mlib
```
Table 7-3, -m Macro, shows the options that compose the -m macro and the information that they provide to the Compiler.

Table 7-3: -m Macro

<table>
<thead>
<tr>
<th>Option</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>-t</td>
<td>Translate M code to C/C++ code.</td>
</tr>
<tr>
<td>-W main</td>
<td>Produce a wrapper file suitable for a stand-alone application.</td>
</tr>
<tr>
<td>-L C</td>
<td>Generate C code as the target language.</td>
</tr>
<tr>
<td>-T link:exe</td>
<td>Create an executable as the output.</td>
</tr>
<tr>
<td>-h</td>
<td>Automatically, find and compile helper functions included in the source M-file.</td>
</tr>
<tr>
<td>libmmfile.mlib</td>
<td>Link to this shared library whenever necessary.</td>
</tr>
</tbody>
</table>

Changing Macro Options. You can change the meaning of a macro option by editing the corresponding macro_option file bundle file in <matlab>/toolbox/compiler/bundles. For example, to change the -x macro, edit the file macro_option_x in the bundles directory.

Setting Up Default Options

If you have some command line options that you wish always to pass to mcc, you can do so by setting up an mccstartup file. Create a text file containing the desired command line options and name the file mccstartup. Place this file in one of two directories:

- The current working directory, or
- Your preferences directory ($HOME/.matlab/R13 on UNIX, <system root>\profiles\<user>\application data\mathworks\matlab\R13 on PC)

mcc searches for the mccstartup file in these two directories in the order shown above. If it finds an mccstartup file, it reads it and processes the options within the file as if they had appeared on the mcc command line before any actual
command line options. Both the `mccstartup` file and the `-B` option are processed the same way.

**Note** If you need to change the meaning of a macro to satisfy your individual requirements, you should create or modify your `mccstartup` file in the preferences directory. Changing the file `macro_option_x` in the bundles directory changes the option for all Compiler users. To see the name of your preferences directory, type `prefdir` at the command prompt.

---

**Setting a MATLAB Path in the Stand-Alone MATLAB Compiler**

Unlike the MATLAB version of the Compiler, which inherits a MATLAB path from MATLAB, the stand-alone version has no initial path. If you want to set up a default path, you can do so by making an `mccpath` file. To do this:

1. Create a text file containing the text `-I <your_directory_here>` for each directory you want on the default path, and name this file `mccpath`. (Alternately, you can call the `mccsavepath` M-function from MATLAB to create an `mccpath` file.)
2. Place this file in your preferences directory. To do so, run the following commands at the MATLAB prompt:
   ```
   cd(prefdir); mccsavepath;
   ```
   These commands save your current MATLAB path to a file named `mccpath` in your user preferences directory. (Type `prefdir` to see the name of your preferences directory.)

The stand-alone version of the MATLAB Compiler searches for the `mccpath` file in your current directory and then your preferences directory. If it finds an `mccpath` file, it processes the directories specified within the file and uses them to initialize its search path. Note that you may still use the `-I` option on the command line or in `mccstartup` files to add other directories to the search path. Directories specified this way are searched after those directories specified in the `mccpath` file.
Conflicting Options on Command Line

If you use conflicting options, the Compiler resolves them from left to right, with the rightmost option taking precedence. For example, using the equivalencies in Table 7-2, Macro Options,

\[
mcc -m -W none \text{ test.m}
\]

is equivalent to

\[
mcc -t -W main -L C -T link:exe -h -W none \text{ test.m}
\]

In this example, there are two conflicting \(-W\) options. After working from left to right, the Compiler determines that the rightmost option takes precedence, namely, \(-W\) none, and the Compiler does not generate a wrapper.

Note  Macros and regular options may both affect the same settings and may therefore override each other depending on their order in the command line.

Handling Full Pathnames

If you specify a full pathname to an M-file on the \texttt{mcc} command line, the Compiler:

1. Breaks the full name into the corresponding path- and filenames (\texttt{<path>} and \texttt{<file>}).
2. Replaces the full pathname in the argument list with “\texttt{-I <path> <file>}”.

For example,

\[
mcc -m /\text{home}/\text{user}/\text{myfile.m}
\]

would be treated as

\[
mcc -m -I /\text{home}/\text{user} \text{ myfile.m}
\]

In rare situations, this behavior can lead to a potential source of confusion. For example, suppose you have two different M-files that are both named \texttt{myfile.m} and they reside in /\text{home}/\text{user}/\text{dir1} and /\text{home}/\text{user}/\text{dir2}. The command

\[
mcc -m -I /\text{home}/\text{user}/\text{dir1} /\text{home}/\text{user}/\text{dir2}/\text{myfile.m}
\]

would be equivalent to
mcc

mcc -m -I /home/user/dir1 -I /home/user/dir2 myfile.m

The Compiler finds the myfile.m in dir1 and compiles it instead of the one in dir2 because of the behavior of the -I option. If you are concerned that this might be happening, you can specify the -v option and then see which M-file the Compiler parses. The -v option prints the full pathname to the M-file.

**Note**  The Compiler produces a warning (specified_file_mismatch) if a file with a full pathname is included on the command line and it finds it somewhere else.

**Compiling Embedded M-Files**

If the M-file you are compiling calls other M-files, you can list the called M-files on the command line. Doing so causes the MATLAB Compiler to build all the M-files into a single MEX-file, which usually executes faster than separate MEX-files. Note, however, that the single MEX-file has only one entry point regardless of the number of input M-files. The entry point is the first M-file on the command line. For example, suppose that bell.m calls watson.m.

Compiling with

```
mcc -x bell watson
```

creates bell.mex. The entry point of bell.mex is the compiled code from bell.m. The compiled version of bell.m can call the compiled version of watson.m. However, compiling as

```
mcc -x watson bell
```

creates watson.mex. The entry point of watson.mex is the compiled code from watson.m. The code from bell.m never gets executed.

As another example, suppose that x.m calls y.m and that y.m calls z.m. In this case, make sure that x.m is the first M-file on the command line. After x.m, it does not matter which order you specify y.m and z.m.
MATLAB Compiler Option Flags

The MATLAB Compiler option flags perform various functions that affect the generated code and how the Compiler behaves. Table 7-4, Compiler Option Categories, shows the categories of options.

<table>
<thead>
<tr>
<th>Category</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>Macros</td>
<td>The macro options simplify the compilation process by combining the most common compilation tasks into single options.</td>
</tr>
<tr>
<td>Code Generation</td>
<td>These options affect the actual code that the Compiler generates. For example, <code>-L</code> specifies the target language as either C or C++.</td>
</tr>
<tr>
<td>Compiler and Environment</td>
<td>These options provide information to the Compiler such as where to put <code>-d</code> and find <code>-I</code> particular files.</td>
</tr>
<tr>
<td>mbuild/mex</td>
<td>These options provide information for the mbuild and/or mex scripts.</td>
</tr>
</tbody>
</table>

The remainder of this reference page is subdivided into sections that correspond to the Compiler option categories. Each section provides a full description of all of the options in the category.

Macro Options

The macro options provide a simplified way to accomplish basic compilation tasks.

-g (Debug). This option is a macro that is equivalent to

- `G -A debugline:on -O none`

or

- `B macro_option_g`
In addition to the -G option, the -g option includes the -A debugline:on option. This will have an impact on performance of the generated code. If you want to have debugging information, but do not want the performance degradation associated with the debug line information, use -g -A debugline:off. The -g option also includes the -O none option, causing all compiler optimizations to be turned off. If you want to have some optimizations on, you may specify them after the debug option.

-m (Stand-Alone C). Produce a stand-alone C application. It includes helper functions by default (-h), and then generates a stand-alone C wrapper (-W main). In the final stage, this option compiles your code into a stand-alone executable and links it to the MATLAB C/C++ Math Library (-T link:exe). For example, to translate an M-file named mymfile.m into C and to create a stand-alone executable that can be run without MATLAB, use

   mcc -m mymfile

The -m option is equivalent to the series of options

   -W main -L C -t -T link:exe -h libmmyfile.mlib

or

   -B macro_option_m

-p (Stand-Alone C++). Produce a stand-alone C++ application. It includes helper functions by default (-h), and then generates a stand-alone C++ wrapper (-W main). In the final stage, this option compiles your code into a stand-alone executable and links it to the MATLAB C/C++ Math Library (-T link:exe). For example, to translate an M-file named mymfile.m into C++ and to create a stand-alone executable that can be run without MATLAB, use

   mcc -p mymfile

The -p option is equivalent to the series of options

   -W main -L Cpp -t -T link:exe -h libmmyfile.mlib

or

   -B macro_option_p
-S (Simulink S-Function). Produce a Simulink S-function that is compatible with
the Simulink S-Function block. For example, to translate an M-file named
mymfile.m into C and to create the corresponding Simulink S-function using
dynamically sized inputs and outputs, use

```bash
mcc -S mymfile
```

The -S option is equivalent to the series of options

```bash
-W simulink -L C -t -T link:mex libmatlbmx.mlib
```
or

```bash
-B macro_option_s
```

-x (MEX-Function). Produce a MEX-function. For example, to translate an M-file
named mymfile.m into C and to create the corresponding MEX-file that can be
called directly from MATLAB, use

```bash
mcc -x mymfile
```

The -x option is equivalent to the series of options

```bash
-W mex -L C -t -T link:mexlibrary libmatlbmx.mlib
```
or

```bash
-B macro_option_x
```

**Bundle Files**

-B ccom (C COM Object). Produce a C COM object. The -B ccom option is
equivalent to the series of options

```bash
-t -W com:<component_name>,<class_name>,<version> -T link:lib
-h libmfile.mlib -i
```

-B cexcel (C Excel COM Object). Produce a C Excel COM object. The -B cexcel
option is equivalent to the series of options

```bash
-B excel:<component_name>,<class_name>,<version> -T link:lib
-h libmfile.mlib -b -i
```

-B csdlgcom (C Handle Graphics COM Object). Produce a C COM object that uses
Handle Graphics. The -B csdlgcom option is equivalent to the series of options
mcc

-B sgl -t -W comhg:<component_name>,<class_name>,<version>
   -T link:lib -h libmmfile.mlib -i

-B csglexcel (C Handle Graphics Excel COM Object). Produce a C Excel COM object
   that uses Handle Graphics. The -B csglexcel option is equivalent to the series
   of options

   -B sgl -t -W excelhg:<component_name>,<class_name>,<version>
   -T link:lib -h libmmfile.mlib -b -i

-B csglsharedlib (C Handle Graphics Shared Library). Produce a C shared library that
   uses Handle Graphics. The -B csglsharedlib option is equivalent to the series
   of options

   -t -W libhg:<shared_library_name> -T link:lib -h libmmfile.mlib
   libmwsglm.mlib

-B cppcom (C++ COM Object). Produce a C++ COM object. The -B cppcom option is
   equivalent to the series of options

   -B ccom:<component_name>,<class_name>,<version> -L cpp

-B cppexcel (C++ Excel COM Object). Produce a C++ Excel COM object. The
   -B cppexcel option is equivalent to the series of options

   -B cexcel:<component_name>,<class_name>,<version> -L cpp

-B cppsglcom (C++ Handle Graphics COM Object). Produce a C++ COM object that
   uses Handle Graphics. The -B cppsglcom option is equivalent to the series
   of options

   -B csglcom:<component_name>,<class_name>,<version> -L cpp

-B cppsglexcel (C++ Handle Graphics Excel COM Object). Produce a C++ Excel COM
   object that uses Handle Graphics. The -B cppsglexcel option is equivalent to
   the series of options

   -B csglexcel:<component_name>,<class_name>,<version> -L cpp

-B cpplib (C++ Library). Produce a C++ library. The -B cpplib option is
   equivalent to the series of options

   -B csharedlib:<shared_library_name> -L cpp -T compile:lib
-B csharedlib (C Shared Library). Produce a C shared library. The -B csharedlib option is equivalent to the series of options

-t -W lib:<shared_library_name> -T link:lib -h libmmfile.mlib

-B pcode (MATLAB P-Code). Produce MATLAB P-code.

The -B pcode option is equivalent to the series of options

-t -L P

The -B sgl option is equivalent to the series of options

-m -W mainhg libmwsglm.mlib

The -B sglcpp option is equivalent to the series of options

-p -W mainhg libmwsglm.mlib

Code Generation Options

-A (Annotation Control for Output Source). Control the type of annotation in the resulting C/C++ source file. The types of annotation you can control are

- M-file code and/or comment inclusion (annotation)
- #line preprocessor directive inclusion (line)
- Whether error messages report the source file and line number (debugline)

To control the M-file code that is included in the generated C/C++ source, use

mcc -A annotation:type
Table 7-5, Code/Comment Annotation Options, shows the available annotation options.

**Table 7-5: Code/Comment Annotation Options**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all</td>
<td>Provides the complete source of the M-file interleaved with the generated C/C++ source. The default is all.</td>
</tr>
<tr>
<td>comments</td>
<td>Provides all of the comments from the M-file interleaved with the generated C/C++ source.</td>
</tr>
<tr>
<td>none</td>
<td>No comments or code from the M-file are added to code.</td>
</tr>
</tbody>
</table>

To control the `#line` preprocessor directives that are included in the generated C/C++ source, use

```
mcc -A line:setting
```

Table 7-6, Line Annotation Options, shows the available `#line` directive settings.

**Table 7-6: Line Annotation Options**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>Adds <code>#line</code> preprocessor directives to the generated C/C++ source code to enable source M-file debugging. <strong>Note:</strong> The page width option is ignored when this is on.</td>
</tr>
<tr>
<td>off</td>
<td>Adds no <code>#line</code> preprocessor directives to the generated C/C++ source code. The default is off.</td>
</tr>
</tbody>
</table>

To control if run-time error messages report the source file and line number, use

```
mcc -A debugline:on
```
Table 7-7, Run-Time Error Annotation Options, shows the available debugline directive settings.

### Table 7-7: Run-Time Error Annotation Options

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>on</td>
<td>Specifies the presence of source file and line number information in run-time error messages.</td>
</tr>
<tr>
<td>off</td>
<td>Specifies no source file and line number information in run-time error messages. The default is off.</td>
</tr>
</tbody>
</table>

For example, to include all of your M-code, including comments, in the generated file and the standard #line preprocessor directives, use

```
mcc -A annotation:all -A line:on
```
or

```
mcc -A line:on  (The default is all for code/comment inclusion.)
```

To include none of your M-code and no #line preprocessor directives, use

```
mcc -A annotation:none -A line:off
```

To include the standard #line preprocessor directives in your generated C/C++ source code as well as source file and line number information in your run-time error messages, use

```
mcc -A line:on -A debugline:on
```

**-F <option> (Formatting)**. Control the formatting of the generated code. Table 7-8, Formatting Options, shows the available options.

### Table 7-8: Formatting Options

<table>
<thead>
<tr>
<th>&lt;Option&gt;</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>list</td>
<td>Generates a table of all the available formatting options.</td>
</tr>
<tr>
<td>expression-indent:n</td>
<td>Sets the number of spaces of indentation for all expressions to n, where n is an integer. The default indent is 4.</td>
</tr>
</tbody>
</table>
Generate C/C++ code that prints filename and line numbers on run-time errors. This option flag is useful for debugging, but causes the executable to run slightly slower. This option is equivalent to

```
mcc -A debugline:on
```

- `-L <language>` (Target Language). Specify the target language of the compilation. Possible values for language are C or Cpp. The default is C. Note that these values are case insensitive.

- `-O <option>` (Optimization Options). Optimize your M-file source code so that the performance of the generated C/C++ code may be faster than the performance of the M-code in the MATLAB interpreter. Table 7-9, Optimization Options, shows the available options.

### Table 7-9: Optimization Options

<table>
<thead>
<tr>
<th><code>&lt;Option&gt;</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-0 list</code></td>
<td>Lists all available optimizations.</td>
</tr>
<tr>
<td><code>-0 all</code></td>
<td>Turns on all optimizations; all is the default. Equivalent to <code>-B opt_bundle_all</code>.</td>
</tr>
</tbody>
</table>
-u **(Number of Inputs).** Provide more control over the number of valid inputs for your Simulink S-function. This option specifically sets the number of inputs ($u$) for your function. If -u is omitted, the input will be dynamically sized. (Use this with the -S option.)

-W **<type> (Function Wrapper).** Control the generation of function wrappers for a collection of Compiler-generated M-files. You provide a list of functions and the Compiler generates the wrapper functions and any appropriate global variable definitions. Table 7-10, Function Wrapper Types, shows the valid options.

<table>
<thead>
<tr>
<th><strong>&lt;Type&gt;</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>mex</td>
<td>Produces a mexFunction() interface.</td>
</tr>
<tr>
<td>main</td>
<td>Produces a POSIX shell main() function.</td>
</tr>
<tr>
<td>simulink</td>
<td>Produces a Simulink C MEX S-function interface.</td>
</tr>
</tbody>
</table>
### Caution

When generating function wrappers, you must specify all M-files that are being linked together on the command line. These files are used to produce the initialization and termination functions as well as global variable definitions. If the functions are not specified in this manner, undefined symbols will be produced at link time or run-time crashes may occur.
-y (Number of Outputs). Provide more control over the number of valid outputs for your Simulink S-function. This option specifically sets the number of outputs \( (y) \) for your function. If -y is omitted, the output will be dynamically sized. (Use this with the -S option.)

**Compiler and Environment Options**

- b (Visual Basic File). Generate a Visual Basic file (.bas) that contains the Microsoft Excel Formula Function interface to the Compiler-generated COM object. When imported into the workbook Visual Basic code, this code allows the MATLAB function to be seen as a cell formula function.

-B <filename>:[<a1>,<a2>,...,<an>] (Bundle of Compiler Settings). Replace -B <filename>:[<a1>,<a2>,...,<an>] on the mcc command line with the contents of the specified file. The file should contain only mcc command line options and corresponding arguments and/or other filenames. The file may contain other -B options.

A bundle file can include replacement parameters for Compiler options that accept names and version numbers. For example, there is a bundle file for C shared libraries, csharedlib, that consists of

\[-t -W \%1\% -T link:lib -h libmmfile.mlib\]

To invoke the Compiler to produce a C shared library using this bundle, you would use

mcc -B csharedlib:mysharedlib <f1>,<f2>,...

In general, each \% in the bundle file will be replaced with the corresponding option specified to the bundle file. Use \% to include a % character. It is an error to have too many or too few options to the bundle file.

You can place options that you always set in an mccstartup file. For more information, see “Setting Up Default Options” on page 7-27.
**mcc**

**Note** You can use the `-B` option with a replacement expression as is at the DOS or UNIX prompt. To use `-B` with a replacement expression at the MATLAB prompt, you must enclose the expression that follows the `-B` in single quotation marks. For example:

```
>>mcc -B 'csharedlib:libtimefun' weekday data tic calendar toc
```

This table shows the available bundle files.

<table>
<thead>
<tr>
<th>Bundle File Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>ccom</td>
<td><code>-t -W com:&lt;component_name&gt;,&lt;class_name&gt;,&lt;version&gt; -T link:lib -h libmmfile.mlib -i</code></td>
</tr>
<tr>
<td>cexcel</td>
<td><code>-B excel:&lt;component_name&gt;,&lt;class_name&gt;,&lt;version&gt; -T link:lib -h libmmfile.mlib -b -i</code></td>
</tr>
<tr>
<td>csglcom</td>
<td><code>-B sgl -t -W comhg:&lt;component_name&gt;,&lt;class_name&gt;,&lt;version&gt; -T link:lib -h libmmfile.mlib</code></td>
</tr>
<tr>
<td>csglexcel</td>
<td><code>-B sgl -t -W excelhg:&lt;component_name&gt;,&lt;class_name&gt;,&lt;version&gt; -T link:lib -h libmmfile.mlib -b -i</code></td>
</tr>
<tr>
<td>csglsharedlib</td>
<td><code>-t -W libhg:&lt;shared_library_name&gt; -T link:lib -h libmmfile.mlib libcwsoglml.lib</code></td>
</tr>
<tr>
<td>cppcom</td>
<td><code>-B ccom:&lt;component_name&gt;,&lt;class_name&gt;,&lt;version&gt; -L cpp</code></td>
</tr>
<tr>
<td>cppexcel</td>
<td><code>-B cexcel:&lt;component_name&gt;,&lt;class_name&gt;,&lt;version&gt; -L cpp</code></td>
</tr>
<tr>
<td>cppsglcom</td>
<td><code>-B chgcom:&lt;component_name&gt;,&lt;class_name&gt;,&lt;version&gt; -L cpp</code></td>
</tr>
<tr>
<td>cppsglexcel</td>
<td><code>-B csglexcel:&lt;component_name&gt;,&lt;class_name&gt;,&lt;version&gt; -L cpp</code></td>
</tr>
<tr>
<td>cpplib</td>
<td><code>-B csharedlib:&lt;shared_library_name&gt; -L cpp -T compile:lib</code></td>
</tr>
<tr>
<td>csharedlib</td>
<td><code>-t -W lib:&lt;shared_library_name&gt; -T link:lib -h libmmfile.mlib</code></td>
</tr>
<tr>
<td>macro_default</td>
<td><code>-O all</code></td>
</tr>
<tr>
<td>macro_option_g</td>
<td><code>-G -A debugline:on -O none</code></td>
</tr>
</tbody>
</table>
When used with a macro option, generate C code but do not invoke `mex` or `mbuild`, i.e., do not produce a MEX-file or stand-alone application. This is equivalent to `-T codegen` placed at the end of the `mcc` command line.

**-d <directory> (Output Directory)**. Place the output files from the compilation in the directory specified by the `-d` option.

**-h (Helper Functions)**. Compile helper functions. Any helper functions that are called will be compiled into the resulting MEX or stand-alone application. The `-m` option automatically compiles all helper functions, so `-m` effectively calls `-h`. Using the `-h` option is equivalent to listing the M-files explicitly on the `mcc` command line.

### Bundle File Name | Contents
---|---
macro_option_m | `-W main -L C -t -T link:exe -h libmfile.mlib`
macro_option_p | `-W main -L Cpp -t -T link:exe -h libmfile.mlib`
macro_option_S | `-W simulink -L C -t -T link:mex libmatlbmx.mlib`
macro_option_x | `-W mex -L C -t -T link:mexlibrary libmatlbmx.mlib`

<table>
<thead>
<tr>
<th>Bundle File Name</th>
<th>Contents</th>
</tr>
</thead>
</table>
| opt_bundle_all | `-0 fold_scalar_mxarrays:on -0 fold_non_scalar_mxarrays:on -0 optimize_integer_for_loops:on -0 array_indexing:on -0 optimize_conditionals:on`
| opt_bundle_none | `-0 fold_scalar_mxarrays:off -0 fold_non_scalar_mxarrays:off -0 optimize_integer_for_loops:off -0 array_indexing:off -0 optimize_conditionals:off -0 speculate:off`
| pcode | `-t -L P`
| sgl | `-m -W mainhg libmwsglm.mlib`
| sglcpp | `-p -W mainhg libmwsglm.mlib`
The `-h` option purposely does not include built-in functions or functions that
appear in the MATLAB M-File Math Library portion of the C/C++ Math
Libraries. This prevents compiling functions that are already part of the C/C++
Math Libraries. If you want to compile these functions as helper functions, you
should specify them explicitly on the command line. For example, use

```bash
mcc -m minimize_it fminsearch
```

instead of

```bash
mcc -m -h minimize_it
```

**-i (Include Exported Interfaces).** Cause the Compiler to include only the M-files that
are specified on the command line as exported interfaces. If additional M-files
are compiled as a result of being located by the `-h` option, they are not included
in the exported interface that is produced by the MATLAB Compiler.

**-I <directory> (Directory Path).** Add a new directory path to the list of included
directories. Each `-I` option adds a directory to the end of the current search
path. For example,

```bash
-I <directory1> -I <directory2>
```

would set up the search path so that `directory1` is searched first for M-files,
followed by `directory2`. This option is important for stand-alone compilation
where the MATLAB path is not available.

**-o <outputfile>.** Specify the basename of the final executable output (stand-alone
applications only) of the Compiler. A suitable, possibly platform-dependent,
extension is added to the specified basename (e.g., `.exe` for PC stand-alone
applications).

**Note** You cannot use this option to specify a different name for a MEX-file.

**-t (Translate M to C/C++).** Translate M-files specified on the command line to
C/C++ files.

**-T <target> (Output Stage).** Specify the desired output stage. Table 7-11, Output
Stage Options, gives the possible values of `target`. 

7-44
### Table 7-11: Output Stage Options

<table>
<thead>
<tr>
<th>&lt;Target&gt;</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>codegen</td>
<td>Translates M-files to C/C++ files and generates a wrapper file. The default is codegen.</td>
</tr>
<tr>
<td>compile:mex</td>
<td>Same as codegen plus compiles C/C++ files to object form suitable for linking into a Simulink S-function MEX-file.</td>
</tr>
<tr>
<td>compile:mexlibrary</td>
<td>Same as codegen plus compiles C/C++ files to object form suitable for linking into an ordinary (non-S-function) MEX-file.</td>
</tr>
<tr>
<td>compile:exe</td>
<td>Same as codegen plus compiles C/C++ files to object form suitable for linking into a standalone executable.</td>
</tr>
<tr>
<td>compile:lib</td>
<td>Same as codegen plus compiles C/C++ files to object form suitable for linking into a shared library/DLL.</td>
</tr>
<tr>
<td>link:mex</td>
<td>Same as compile:mex plus links object files into a Simulink S-function MEX-file.</td>
</tr>
<tr>
<td>link:mexlibrary</td>
<td>Same as compile:mexlibrary plus links object files into an ordinary (non-S-function) MEX-file.</td>
</tr>
<tr>
<td>link:exe</td>
<td>Same as compile:exe plus links object files into a standalone executable.</td>
</tr>
<tr>
<td>link:lib</td>
<td>Same as compile:lib plus links object files into a shared library/DLL.</td>
</tr>
</tbody>
</table>

mex and mexlibrary use the mex script to build a MEX-file; exe uses the mbuild script to build an executable; lib uses mbuild to build a shared library.
-v (Verbose). Display the steps in compilation, including
- The Compiler version number
- The source filenames as they are processed
- The names of the generated output files as they are created
- The invocation of `mex` or `mbuild`

The `-v` option passes the `-v` option to `mex` or `mbuild` and displays information about `mex` or `mbuild`.

-w (Warning). Display warning messages. Table 7-12, Warning Option, shows the various ways you can use the `-w` option.

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(no <code>-w</code> option)</td>
<td>Default; displays only serious warnings.</td>
</tr>
<tr>
<td><code>-w list</code></td>
<td>Generates a table that maps <code>&lt;string&gt;</code> to warning message for use with enable, disable, and error. Appendix B, “Error and Warning Messages” lists the same information.</td>
</tr>
<tr>
<td><code>-w</code></td>
<td>Enables complete warnings.</td>
</tr>
<tr>
<td><code>-w disable[&lt;string&gt;]</code></td>
<td>Disables specific warning associated with <code>&lt;string&gt;</code>. Appendix B, “Error and Warning Messages” lists the valid <code>&lt;string&gt;</code> values. Leave off the optional <code>&lt;string&gt;</code> to apply the disable action to all warnings.</td>
</tr>
</tbody>
</table>
-Y <license.dat File>. Use license information in license.dat file when checking out a Compiler license.

mbuild/mex Options

-f <filename> (Specifying Options File). Use the specified options file when calling mex or mbuild. This option allows you to use different compilers for different invocations of the MATLAB Compiler. This option is a direct pass-through to the mex or mbuild script. See “External Interfaces/API” in the MATLAB documentation for more information about using this option with the mex script.

Note Although this option works as documented, we suggest that you use mex -setup or mbuild -setup to switch compilers.

-G (Debug Only). Cause mex or mbuild to invoke the C/C++ compiler with the appropriate C/C++ compiler options for debugging. You should specify -G if you want to debug the MEX-file or stand-alone application with a debugger.

-M "string" (Direct Pass Through). Pass string directly to the mex or mbuild script. This provides a useful mechanism for defining compile-time options, e.g., -M "-Dmacro=value".
**Note**  Multiple -M options do not accumulate; only the last -M option is used.

-**z** <path> *(Specifying Library Paths).* Specify the path to use for library and include files. This option uses the specified path for compiler libraries instead of the path returned by `matlabroot`.

**Examples**

Make a C translation and a MEX-file for `myfun.m`:
```
mcc -x myfun
```

Make a C translation and a stand-alone executable for `myfun.m`:
```
mcc -m myfun
```

Make a C++ translation and a stand-alone executable for `myfun.m`:
```
mcc -p myfun
```

Make a C translation and a Simulink S-function for `myfun.m` (using dynamically sized inputs and outputs):
```
mcc -S myfun
```

Make a C translation and a Simulink S-function for `myfun.m` (explicitly calling for one input and two outputs):
```
mcc -S -u 1 -y 2 myfun
```

Make a C translation and stand-alone executable for `myfun.m`. Look for `myfun.m` in the `/files/source` directory, and put the resulting C files and executable in the `/files/target` directory:
```
mcc -m -I /files/source -d /files/target myfun
```

Make a C translation and a MEX-file for `myfun.m`. Also translate and include all M-functions called directly or indirectly by `myfun.m`. Incorporate the full text of the original M-files into their corresponding C files as C comments:
```
mcc -x -h -A annotation:all myfun
```

Make a generic C translation of `myfun.m`:
mcc -t -L C myfun

Make a generic C++ translation of myfun.m:

mcc -t -L Cpp myfun

Make a C MEX wrapper file from myfun1.m and myfun2.m:

mcc -W mex -L C myfun1 myfun2

Make a C translation and a stand-alone executable from myfun1.m and myfun2.m (using one mcc call):

mcc -m myfun1 myfun2

Make a C translation and a stand-alone executable from myfun1.m and myfun2.m (by generating each output file with a separate mcc call):

mcc -t -L C myfun1  % Yields myfun1.c
mcc -t -L C myfun2  % Yields myfun2.c
mcc -W main -L C myfun1 myfun2   % Yields myfun1_main.c
mcc -T compile:exe myfun1.c   % Yields myfun1.o
mcc -T compile:exe myfun2.c   % Yields myfun2.o
mcc -T compile:exe myfun1_main.c  % Yields myfun1_main.o
mcc -T link:exe myfun1.o myfun2.o myfun1_main.o

**Note** On PCs, filenames ending with .o above would actually end with .obj.

Compile plus1.m into an Excel add-in:

mcc -B 'cexcel:addin:addin:1.0' plus1.m
mcc
MATLAB Compiler
Quick Reference

This appendix summarizes the Compiler options and provides brief descriptions of how to perform common tasks.

Common Uses of the Compiler (p. A-2)  Brief summary of how to use the Compiler
mcc (p. A-4)  Quick reference table of Compiler options
Common Uses of the Compiler

This section summarizes how to use the MATLAB Compiler to generate some of its more standard results. The first four examples take advantage of the macro options.

Create a MEX-File. To translate an M-file named `mymfile.m` into C and to create the corresponding C MEX-file that can be called directly from MATLAB, use

```bash
mcc -x mymfile
```

Create a Simulink S-Function. To translate an M-file named `mymfile.m` into C and to create the corresponding Simulink S-function using dynamically sized inputs and outputs, use

```bash
mcc -S mymfile
```

Create a Stand-Alone C Application. To translate an M-file named `mymfile.m` into C and to create a stand-alone executable that can be run without MATLAB, use

```bash
mcc -m mymfile
```

Create a Stand-Alone C++ Application. To translate an M-file named `mymfile.m` into C++ and to create a stand-alone executable that can be run without MATLAB, use

```bash
mcc -p mymfile
```

Create a Stand-Alone C Graphics Library Application. To translate an M-file named `mymfile.m` that contains Handle Graphics functions into C and to create a stand-alone executable that can be run without MATLAB, use

```bash
mcc -B sgl mymfile
```

Create a Stand-Alone C++ Graphics Library Application. To translate an M-file named `mymfile.m` that contains Handle Graphics functions into C++ and to create a stand-alone executable that can be run without MATLAB, use

```bash
mcc -B sglcpp mymfile
```

Create a C Library. To create a C library, use

```bash
mcc -m -W lib:libfoo -T link:lib foo.m
```
Common Uses of the Compiler

Create a C++ Library. To create a C++ library, use

```
mcc -p -W lib:libfoo -T compile:lib foo.m
```

Create a C Shared Library. To create a C shared library that performs specialized calculations that you can call from your own programs, use

```
mcc -W lib:mylib -L C -T link:lib -h Function1 Function2
```

Create MATLAB P-Code. To translate an M-file named `mymfile.m` into MATLAB P-code, use

```
mcc -B pcode mymfile
```

**Note** You can add the `-g` option to any of these for debugging purposes.
## mcc

Bold entries in the Comment/Options column indicate default values.

<table>
<thead>

Error and Warning Messages

This appendix lists and describes error messages and warnings generated by the MATLAB Compiler. Compile-time messages are generated during the compile or link phase. It is useful to note that most of these compile-time error messages should not occur if MATLAB can successfully execute the corresponding M-file. Run-time messages are generated when the executable program runs.

Use this reference to

- Confirm that an error has been reported
- Determine possible causes for an error
- Determine possible ways to correct an error

When using the MATLAB Compiler, if you receive an internal error message, record the specific message and report it to Technical Support at The MathWorks at support@mathworks.com.

Compile-Time Errors (p. B-2) Error messages generated at compile time
Warning Messages (p. B-11) User-controlled warnings generated by the Compiler
Run-Time Errors (p. B-18) Errors generated by the Compiler into your code
Compile-Time Errors

Error: An error occurred while shelling out to `mex/mbuild` (error code = `errno`). Unable to build executable (specify the `-v` option for more information). The Compiler reports this error if `mbuild` or `mex` generates an error.

Error: An error occurred writing to file "filename": `reason`. The file could not be written. The reason is provided by the operating system. For example, you may not have sufficient disk space available to write the file.

Error: Cannot recompile M-file "filename" because it is already in library "libraryname". A procedure already exists in a library that has the same name as the M-file that is being compiled. For example:

```
mcc -x sin.m    % Incorrect
```

Error: Cannot write file "filename" because MCC has already created a file with that name, or a file with that name was specified as a command line argument. The Compiler has been instructed to generate two files with the same name. For example:

```
mcc -W lib:liba liba -t % Incorrect
```

Error: Could not check out a Compiler license. No additional Compiler licenses are available for your workgroup.

Error: Could not find license file "filename". (Windows only) The `license.dat` file could not be found in `<MATLAB>\bin`.

Error: Could not run mbuild. The MATLAB C/C++ Math Library must be installed in order to build stand-alone applications. Install the MATLAB C/C++ Math Library.

Error: File: "filename" not found. A specified file could not be found on the path. Verify that the file exists and that the path includes the file's location. You can use the `-I` option to add a directory to the search path

Error: File: "filename" is a script M-file which cannot be compiled with the current Compiler. The MATLAB Compiler cannot compile script M-files. To learn how to convert script M-files to function M-files, see “Converting Script M-Files to Function M-Files” on page 3-10.

Error: File: `filename` Line: `# Column: ` # != is not a MATLAB operator. Use `~=` instead. Use the MATLAB relational operator `~=` (not equal).
If you use ordinary array indexing ( ) to index into an expression, it must be
last in the index expression. For example, you can use X(1).value and
X{2}(1), but you cannot use X.value(1) or X{1}{2}.

Error: File: filename Line: # Column: # A CONTINUE may only be used within a FOR or WHILE
loop. Use Continue to pass control to the next iteration of a for or while loop.

Error: File: filename Line: # Column: # A function declaration cannot appear within a script
M-file. There is a function declaration in the file to be compiled, but it is not at
the beginning of the file. Scripts cannot have any function declarations;
function M-files must start with a function.

Error: File: filename Line: # Column: # Assignment statements cannot produce a result. An
assignment statement cannot be used in a place where an expression, but not
a statement, is expected. In particular, this message often identifies errors
where an assignment was used, but an equality test was intended. For
example:

if x == y, z = w; end % Correct
if x = y, z = w; end % Incorrect

Error: File: filename Line: # Column: # A variable cannot be made storageclass1 after being
used as a storageclass2. You cannot change a variable's storage class (global/
local/persistent). Even though MATLAB allows this type of change in scope, the
Compiler does not.

Error: File: filename Line: # Column: # An array for multiple LHS assignment must be a vector.
If the left-hand side of a statement is a multiple assignment, the list of
left-hand side variables must be a vector. For example:

[p1, p2, p3] = myfunc(a) % Correct
[p1; p2; p3] = myfunc(a) % Incorrect

Error: File: filename Line: # Column: # An array for multiple LHS assignment cannot be
empty. If the left-hand side of a statement is a multiple assignment, the list of
left-hand side variables cannot be empty. For example:

[p1, p2, p3] = myfunc(a) % Correct
[ ] = myfunc(a) % Incorrect
Error: File: `filename` Line: # Column: # An array for multiple LHS assignment cannot contain token. If the left-hand side of a statement is a multiple assignment, the vector cannot contain this token. For example, you cannot assign to constants.

```matlab
[p1] = myfunc(a) % Correct
[3] = myfunc(a) % Incorrect
```

Error: File: `filename` Line: # Column: # Expected a variable, function, or constant, found "string". There is a syntax error in the specified line. See the online MATLAB Function Reference pages.

Error: File: `filename` Line: # Column: # Expected one of , ; % or EOL, got "string". There is a syntax error in the specified line. See the online MATLAB Function Reference pages.

Error: File: `filename` Line: # Column: # Functions cannot be indexed using {} or . indexing. You cannot use the cell array constructor,{}, or the structure field access operator, ., to index into a function.

Error: File: `filename` Line: # Column: # Indexing expressions cannot return multiple results. There is an assignment in which the left-hand side takes multiple values, but the right-hand side is not a function call but rather a structure access. For example:

```matlab
[x, y] = f(z) % Correct
[x, y] = f.z % Incorrect
```

Error: File: `filename` Line: # Column: # Invalid multiple left-hand-side assignment. For example, you try to assign to constants

```matlab
[] = sin(1); % Incorrect
```

Error: File: `filename` Line: # Column: # MATLAB assignment cannot be nested. You cannot use a syntax such as `x = y = 2`. Use `y = 2, x = y` instead.

Error: File: `filename` Line: # Column: # Missing operator, comma, or semicolon. There is a syntax error in the file. Syntactically, an operator, a comma, or a semicolon is expected, but is missing. For example:

```matlab
if x == y, z = w; end % Correct
if x == y, z = w end % Incorrect
```
Error: File: filename Line: # Column: # Missing variable or function. An illegal name was used for a variable or function. For example:

\[
x \quad \text{Correct}
\]
\[
_x \quad \text{Incorrect}
\]

Error: File: filename Line: # Column: # Only functions can return multiple values. In this example, foo must be a function, it cannot be a variable.

\[
[a, b] = \text{foo};
\]

Error: File: filename Line: # Column: # "string1" expected, "string2" found. There is a syntax error in the specified line. See the online MATLAB Function Reference pages accessible from the Help browser.

Error: File: filename Line: # Column: # The end operator can only be used within an array index expression. You can use the end operator in an array index expression such as \(\text{sum}(A(:, \text{end}))\). You cannot use the end operator outside of such an expression, for example: \(y = 1 + \text{end}\).

Error: File: filename Line: # Column: # The name "parametername" occurs twice as an input parameter. The variable names specified on the function declaration line must be unique. For example:

\[
\text{function foo(bar1, bar2)} \quad \text{Correct}
\]
\[
\text{function foo(bar, bar)} \quad \text{Incorrect}
\]

Error: File: filename Line: # Column: # The name "parametername" occurs twice as an output parameter. The variable names specified on the function declaration line must be unique. For example:

\[
\text{function [bar1, bar2] = foo} \quad \text{Correct}
\]
\[
\text{function [bar, bar] = foo} \quad \text{Incorrect}
\]

Error: File: filename Line: # Column: # The "operatorname" operator may only produce a single output. The primitive operator produces only a single output. For example:

\[
x = 1:10; \quad \text{Correct}
\]
\[
[x, y] = 1:10; \quad \text{Incorrect}
\]
Error: File: filename Line: # Column: # The PERSISTENT declaration must precede any use of the variable variablename. In the text of the function, there is a reference to the variable before the persistent declaration.

Error: File: filename Line: # Column: # The single colon operator (:) can only be used within an array index expression. You can only use the : operator by itself as an array index. For example: A(1) = 5; is okay, but y = :; is not.

Error: File: filename Line: # Column: # The variable variablename was mentioned more than once as an input. The argument list has a repeated variable. For example:

$$\text{function } y = \text{myfun}(x, x) \quad \% \text{ Incorrect}$$

Error: File: filename Line: # Column: # The variable variablename was mentioned more than once as an output. The return value vector has a repeated variable. For example:

$$\text{function } [x, x] = \text{myfun}(y) \quad \% \text{ Incorrect}$$

Error: File: filename Line: # Column: # This statement is incomplete. Variable arguments cannot be made global or persistent. The variables varargin and varargout are not like other variables. They cannot be declared either global or persistent. For example:

$$\text{global varargin} \quad \% \text{ Incorrect}$$

Error: File: filename Line: # Column: # Variable argument (varargin) must be last in input argument list. The function call must specify the required arguments first followed by varargin. For example:

$$\text{function } [\text{out1}, \text{out2}] = \text{example1}(a, b, \text{varargin}) \% \text{ Correct}$$
$$\text{function } [\text{out1}, \text{out2}] = \text{example1}(a, \text{varargin}, b) \% \text{ Incorrect}$$

Error: File: filename Line: # Column: # Variable argument (varargout) must be last in output argument list. The function call must specify the required arguments first followed by varargout. For example:

$$\text{function } [i, j, \text{varargout}] = \text{ex2}(x1, y1, x2, y2, \text{val}) \% \text{ Correct}$$
$$\text{function } [i, \text{varargout}, j] = \text{ex2}(x1, y1, x2, y2, \text{val}) \% \text{ Incorrect}$$

Error: File: filename Line: # Column: # variablename has been declared both as GLOBAL and PERSISTENT. Declare variables as either global or persistent.
Error: Found illegal whitespace character in command line option: "string". The strings on the left and right side of the space should be separate arguments to MCC. For example:

\[
\begin{align*}
mcc(-A, 'none') & \quad \% \text{ Correct} \\
mcc(-A none) & \quad \% \text{ Incorrect}
\end{align*}
\]

Error: Improper usage of option -optionname. Type "mcc -?" for usage information. You have incorrectly used a Compiler option. For more information about Compiler options, see “MATLAB Compiler Option Flags” on page 7-31 or type \texttt{mcc -?} at the command prompt.

Error: "languagename" is not a known language. The dialect option was given a language argument for which there is no support yet. For example:

\[
\begin{align*}
mcc -m -D japanese sample.m & \quad \% \text{ Correct} \\
mcc -m -D german sample.m & \quad \% \text{ Incorrect}
\end{align*}
\]

Error: libraryname library not found. MATLAB has been installed incorrectly.

Error: MEX-File "mexfilename" cannot be compiled into P-Code. Only M-files can be compiled into P-code; MEX-files cannot be compiled into P-code.

Error: No source files were specified (? for help). You must provide the Compiler with the name of the source file(s) to compile.

Error: On UNIX, the name of an MLIB-file must begin with the letters "lib". filename does not adhere to this rule. The mlib file specified on the command line does not start with the letters "lib" and the file being compiled uses procedures in that library.

Error: "optionname" is not a valid -option option argument. You must use an argument that corresponds to the option. For example:

\[
\begin{align*}
mcc -L Cpp & \quad \% \text{ Correct} \\
mcc -L COBOL & \quad \% \text{ Incorrect}
\end{align*}
\]

Error: Out of memory. Typically, this message occurs because the Compiler requests a larger segment of memory from the operating system than is currently available. Adding additional memory to your system could alleviate this problem.

Error: Previous warning treated as error. When you use the -w error option, this error displays immediately after a warning message.
Error: The argument after the -option option must contain a colon. The format for this argument requires a colon. For more information, see “MATLAB Compiler Option Flags” on page 7-31 or type mcc -? at the command prompt.

Error: The environment variable MATLAB must be set to the MATLAB root directory. On UNIX, the MATLAB and LM_LICENSE_FILE variables must be set. The mcc shell script does this automatically when it is called the first time.

Error: The file filename cannot be written. When generating an mlib file, the Compiler cannot write out the mlib file.

Error: The license manager failed to initialize (error code is errornumber). You do not have a valid Compiler license or no additional Compiler licenses are available.

Error: The option -option is invalid in modename mode (specify -? for help). The specified option is not available.

Error: The option -option must be immediately followed by whitespace (e.g. "proper_example_usage"). These options require additional information, so they cannot be combined.

For example, you can use mcc -vc, but you cannot use mcc -Ac annotation:all.

Error: The options specified will not generate any output files.
Please use one of the following options to generate an executable output file:
-x (generates a MEX-file executable using C)
-m (generates a stand-alone executable using C)
-p (generates a stand-alone executable using C++)
-S (generates a Simulink MEX S-function using C)
-B sgl (generates a stand-alone graphics library executable using C (requires the SGL))
-B sglcpp (generates a stand-alone graphics library executable using C++ (requires the SGL))
-B pcode (generates a MATLAB P-code file)
Or type mcc -? for more usage information. Use one of these options or another option that generates an output file(s). See “MATLAB Compiler Option Flags” on page 7-31 or type mcc -? at the command prompt for more information.
Error: The specified file "filename" cannot be read. There is a problem with your specified file. For example, the file is not readable because there is no read permission.

Error: The -option option cannot be combined with other options. The -V2.0 option must appear separate from other options on the command line. For example:

```
mcc -V2.0 -L Cpp       % Correct
mcc -V2.0L Cpp        % Incorrect
```

Error: The -optionname option requires an argument (e.g. "proper_example_usage"). You have incorrectly used a Compiler option. For more information about Compiler options, see “MATLAB Compiler Option Flags” on page 7-31 or type mcc -? at the command prompt.

Error: This version of MCC does not support the creation of C++ MEX code. You cannot create C++ MEX functions with the current Compiler.

Error: Unable to open file "filename":<string>. There is a problem with your specified file. For example, there is no write permission to the output directory, or the disk is full.

Error: Unable to set license linger interval (error code is errornumber). A license manager failure has occurred. Contact Technical Support at The MathWorks with the full text of the error message.

Error: Uninterpretable number of inputs set on command line "commandline". When generating a Simulink S-function, the inputs specified on the command line was not a number. For example:

```
mcc -S -u 2 sample.m  % Correct
mcc -S -u a sample.m  % Incorrect
```

Error: Uninterpretable number of outputs set on command line "commandline". When generating a Simulink S-function, the outputs specified on the command line was not a number. For example:

```
mcc -S -y 2 sample.m  % Correct
mcc -S -y a sample.m  % Incorrect
```

Error: Uninterpretable width set on command line "commandline". The argument to the page width option was not interpretable as a number.
Error: Unknown annotation option: \textit{optionname}. An invalid string was specified after the \texttt{-A} option. For a complete list of the valid annotation options, see “MATLAB Compiler Option Flags” on page 7-31 or type \texttt{mcc -?} at the command prompt.

Error: Unknown typesetting option: \textit{optionname}. The valid typesetting options available with \texttt{-F} are \texttt{expression-indent:n}, \texttt{list}, \texttt{page-width}, and \texttt{statement-indent:n}.

Error: Unknown warning enable/disable string: \textit{warningstring}. \texttt{-w enable:}, \texttt{-w disable:}, and \texttt{-w error:} require you to use one of the warning string identifiers listed in the “Warning Messages” on page B-11.

Error: Unrecognized option: \texttt{-option}. The option is not one of the valid options for this version of the Compiler. See “MATLAB Compiler Option Flags” on page 7-31 for a complete list of valid options for MATLAB Compiler 3.0 or type \texttt{mcc -?} at the command prompt.

Error: Use "V2.0" to specify desired version. You specified \texttt{-V} without a version number. You must use \texttt{-V2.0} if you specify a version number.

Error: \texttt{versionnumber} is not a valid version number. Use "V2.0". If you specify a Compiler version number, it must be \texttt{-V2.0}. The default is \texttt{-V2.0}.
Warning Messages

This section lists the warning messages that the MATLAB Compiler can generate. Using the -w option for `mcc`, you can control which messages are displayed. Each warning message contains a description and the warning message identifier string (in parentheses) that you can enable or disable with the -w option. For example, to enable the display of warnings related to undefined variables, you can use

```
mcc -w enable:undefined_variable
```

To enable all warnings except those generated by the `save` command, use

```
mcc -w enable -w disable:save_options
```

To display a list of all the warning message identifier strings, use

```
mcc -w list
```

For additional information about the -w option, see “MATLAB Compiler Option Flags” on page 7-31.

**Warning:** (PM) **Warning:** message.  *(path_manager_warning)* The path manager can experience file I/O problems when reading the directory structure *(permissions)*.

**Warning:** (PMI): **Warning:** message.  *(path_manager_inform)* This is an informational path manager message.

**Warning:** A line has number characters, violating the maximum page width width. *(max_page_width_violation)* To increase the maximum page width, use the -F page-width:n option and set n to a larger value.

**Warning:** File: filename Line: #: Column: #: A BREAK statement appeared outside of a loop. This BREAK is interpreted as a RETURN. *(break_without_loop)* The break statement should be used in conjunction with the for or while statements. When not used in conjunction with these statements, the break statement acts as a return from a function.
Warning: File: filename Line: # Column: # The call to function "functionname" on this line could not be bound to a function that is known at compile time. A run-time error will occur if this code is executed.  (no_matching_function) The called function was not found on the search path.

Warning: File: filename Line: # Column: # Attempt to clear value when it has not been previously defined.  (clear_undefined_value) The variable was cleared with the clear command prior to being defined.

Warning: File: filename Line: # Column: # Future versions of MATLAB will require that whitespace, a comma, or a semicolon separate elements of a matrix. Please type "help matrix_element_separators" at the MATLAB prompt for more information.  (separator_needed) It is still possible to leave out all separators when constructing a matrix. For example, [5.5.5] has no separators. It is equivalent to [5.5, 0.5].

Warning: File: filename Line: # Column: # References to "functionname" require the C/C++ Graphics Library when executing in stand-alone mode. You must specify -B sgl or -B sglcpp in order to use the C/C++ Graphics Library. A run-time error will occur if the C/C++ Graphics Library is not present.  (using_graphics_function) This warning is produced when a Graphics Library call is present in the code. It is only generated when producing the main or library wrapper and not during normal compilation, unless it is specifically enabled.

Warning: File: filename Line: # Column: # References to "variablename" will produce a run-time error because it is an undefined function or variable.  (undefined_variable_or_unknown_function) This warning appears if you refer to a variable but never provide it with a value. The most likely cause of this warning is when you call a function that is not on the path or it is a method function.

**Note** Inline objects are not supported in this release and will produce this warning when used.

Warning: File: filename Line: # Column: # The #function pragma expects a list of function names.  (pragma_function_missing_names) This pragma informs the MATLAB Compiler that the specified function(s) provided in the list of function names
will be called through an `feval` call. This is used so that the `-h` option will automatically compile the selected functions.

**Warning:** File: `filename` Line: # Column: # The call to function "`functionname`" on this line passed `quantity1` inputs and the function is declared with `quantity2`. A run-time error will occur if this code is executed. *(too_many_inputs)* There is an inconsistency between the number of formal and actual inputs to the function.

**Warning:** File: `filename` Line: # Column: # The call to function "`functionname`" on this line requested `quantity1` outputs and the function is declared with `quantity2`. A run-time error will occur if this code is executed. *(too_many_outputs)* There is an inconsistency between the number of formal and actual outputs for the function.

**Warning:** File: `filename` Line: # Column: # The clear function cannot process the "`optionname`" argument in compiled code. *(clear_cannot_handle_flag)* You cannot use clear variables, clear `mex`, clear functions, or clear `all` in compiled M-code.

**Warning:** File: `filename` Line: # Column: # The clear statement did not specifically list the names of variables to be cleared as constant strings. A run-time error will be reported if this code is executed. *(clear_non_constant_strings)* Use one of the forms of the clear command that contains the names of the variables to be cleared. Use `clear` name or `clear('name')`; do not use `clear(name)`.

**Warning:** File: `filename` Line: # Column: # The Compiler does not support the `optionname` option to save. This option is ignored. *(save_option_ignored)* You cannot use `-ascii`, `-double`, or `-tabs` with the `save` command in compiled M-code.

**Warning:** File: `filename` Line: # Column: # The `filename` provided to load (save) was a cell array or structure index that could possibly expand into a comma separated list. An error will occur at run-time if a comma list is present for the `filename`. *(load_save_filename)* The Compiler needs to know statically the number of variables that are involved in a load or save. If a cell array is involved, the Compiler cannot make that determination, and the generated code may behave differently from MATLAB.

**Warning:** File: `filename` Line: # Column: # The "`functionname`" function is only available in MEX mode. A run-time error will occur if this code is executed in stand-alone mode. *(using_mex_only_function)* This warning is produced if you call any built-in function that is only available in `mex` mode. It is only generated when producing the main or `lib` wrapper and not during normal compilation, unless specifically enabled.
Warning: File: *filename* Line: # Column: # The load statement cannot be translated unless it specifically lists the names of variables to be loaded as constant strings.

(load_without_constant_strings) Use one of the forms of the `load` command that contains the names of the variables to be loaded, for example:

```matlab
load filename num or y = load('filename')
```

Warning: File: *filename* Line: # Column: # The logical expression(s) involving OR and AND operators may have returned a different result in previous versions of MATLAB due to a change in logical operator precedence. Use parentheses to make your code insensitive to this change. Please type "help precedence" for more information.

(and_or_precedence) Starting in MATLAB 6.0, the precedence of the logical AND (`&`) and logical OR (`|`) operators now obeys the standard relationship (AND being higher precedence than OR) and the formal rules of Boolean algebra as implemented in most other programming languages, as well as Simulink and Stateflow.

Previously, MATLAB would incorrectly treat the expression

```matlab
y = a&b | c&d
```

as

```matlab
y = (((a&b) | c) & d);
```

It now correctly treats it as

```matlab
y = (a&b) | (c&d);
```

The form, `y = a&b | c&d`, will not elicit the warning message from the Compiler. We recommend that you use parentheses to get the same behavior now and in the future.

Warning: File: *filename* Line: # Column: # The MATLAB Compiler does not currently support MATLAB object-oriented programming. References to the method "methodname" will produce a run-time error.

(matlab_method_used) This warning occurs if the file being compiled references a function that has only a method definition.

Warning: File: *filename* Line: # Column: # The save statement cannot be translated unless it specifically lists the names of variables to be saved as constant strings.

(save_without_constant_strings) Use one of the forms of the `save` command that contains the names of the variables to be saved, for example:

```matlab
save filename num
```
Warning: File: filename Line: # Column: # The second output argument from the
"functionname" function is only available in MEX mode. A run-time error will occur if this code
is executed in stand-alone mode. (unix_dos_second_argument) The DOS command
can be called with two output arguments. That form cannot be compiled in
stand-alone mode. This warning occurs if the DOS command was called with
two output arguments in a file that is being compiled in stand-alone mode. For
example:

[r, s] = dos('ls'); % Causes a warning when compiling stand-alone

Warning: File: filename Line: # Column: # This load (save) statement referred to variable
"variablename" that was not referenced in the function. (load_save_unreferenced)
This warning occurs if a variable is loaded (saved) via a load (save) command,
but then does not occur elsewhere in scope.

Warning: File: filename Line: # Column: # Unmatched "end". (end_without_block) The
end statement does not have a corresponding for, while, switch, try, or if
statement.

Warning: File: filename Line: # Column: # Unrecognized Compiler pragma "pragmaname".
(unrecognizedPragma) Use one of the Compiler pragmas as described in
Chapter 7, “Reference”.

Warning: File: filename Line: # Column: # name has been used as both a function and a
variable, the variable is ignored. (inconsistent_variable) When a name represents
both a function and a variable, it is used as the function only.

Warning: File: filename Line: # Column: # "variablename" has not been defined prior to use
on this line. (undefined_variable) Variables should be defined prior to use.

Warning: Line: # Column: # Function with duplicate name "functionname" cannot be called.
(duplicateFunctionName) This warning occurs when an M-file contains more
than one function with the same name.

Warning: filename is a P-file being referenced from "filename". NOTE: A link error will be
produced if a call to this function is made from stand-alone mode. (mex_or_p_file) The
Compiler cannot generate a call to a function in a P-file for stand-alone code.
The warning occurs if a call to a function that is defined in a P-file is detected.
Warning: M-file "filename" was specified on the command line with full path of "pathname", but was found on the search path in directory "directoryname" first. 

(specified_file_mismatch) The Compiler detected an inconsistency between the location of the M-file as given on the command line and in the search path. The Compiler uses the location in the search path. This warning occurs when you specify a full pathname on the   \texttt{mcc} command line and a file with the same base name (filename) is found earlier on the search path. This warning is issued in the following example if the file \textit{afile.m} exists in both dir1 and dir2.

\texttt{mcc -x -I /dir1 /dir2/afile.m}

Warning: No M-function source available for "functionname", assuming function \begin{verbatim} [varargout] = functionname(varargin) \end{verbatim} NOTE: This will produce a link error in stand-alone code unless you provide a handwritten definition for this function. 

(using_stub_function) The Compiler found a .p or .mex version of the function and is substituting a generic function declaration in its place.

Warning: Overriding the -F page-width setting to \textit{width} due to presence of \texttt{-A line:on} setting. 

(page_width_override) The -A line:on setting overrides the page width. This warning reminds you that the -F setting, although present, has no effect.

Warning: The function "functionname" is an intrinsic MATLAB function. The signature of the function found in file "filename" does not match the known signature for this function:
known number of inputs = \textit{quant1} found number of inputs = \textit{quant2}
known number of outputs = \textit{quant1} found number of outputs = \textit{quant2}
known varargin used = \textit{quant1} found varargin used = \textit{quant2}
known varargout used = \textit{quant1} found varargout used = \textit{quant2}
known nargout used = \textit{quant1} found nargout used = \textit{quant2}.

(builtin_signature_mismatch) When compiling an M-file that is contained in the MathWorks libraries, the number of inputs/outputs and the signatures to the function must match exactly.

Warning: The file \textit{filename} was repeated on the Compiler command line. (repeated_file) This warning occurs when the same filename appears more than once on the compiler command line. For example:

\texttt{mcc -x sample.m sample.m % Will generate the warning}
Warning: The name of a shared library should begin with the letters "lib". "libraryname" doesn't. (missing_lib_sentinel) This warning is generated if the name of the specified library does not begin with the letters “lib”. This warning is specific to UNIX and does not occur on Windows. For example:

```bash
mcc -t -W lib:liba -T link:lib a0 a1 % No warning
mcc -t -W lib:a -T link:lib a0 a1 % Will generate a warning
```

Warning: The option optionname is ignored in modename mode (specify -? for help). (switch_ignored) Modename = 1.2 or 2.0. Certain options only have meaning in one or the other mode. For example, if you use the -e option, you can't use the -V2.0 option. For more information about Compiler options, see “MATLAB Compiler Option Flags” on page 7-31.

Warning: The specified private directory is not unique. Both "directoryname1" and "directoryname2" are found on the path for this private directory. (duplicate_private_directories) The Compiler cannot distinguish which private function to use. For more information, see “Compiling Private and Method Functions” on page 5-5.
**Run-Time Errors**

**Note** The error messages described in this section are generated by the Compiler into the code exactly as they are written, but are not the only source of run-time errors. You also can receive run-time errors can from the C/C++ Math Libraries; these errors are not documented in this book. Math Library errors do not include the source file and line number information. If you receive such an error and are not certain if it is coming from the C/C++ Math Libraries or your M-code, compile with the -A debugline:on option to get additional information about which part of the M source code is causing the error. For more information about -A (the annotation option), see “MATLAB Compiler Option Flags” on page 7-31.

Run-time Error: File: *filename* Line: # Column: # The call to function "*functionname*" that appeared on this line was not a known function at compile time. The function was not found at compile time.

Run-time Error: File: *filename* Line: # Column: # The call to function "*functionname*" on this line passed *quantity1* inputs and the function is declared with *quantity2*. There is an inconsistency between the formal and actual number of inputs to a function.

Run-time Error: File: *filename* Line: # Column: # The call to function "*functionname*" on this line requested *quantity1* outputs and the function is declared with *quantity2*. There is an inconsistency between the formal and actual number of outputs from a function.

Run-time Error: File: *filename* Line: # Column: # The clear statement did not specifically list the names of variables to be cleared as constant strings. Use one of the forms of the clear command that contains the names of the variables to be cleared, for example:

```
clear name
```

Run-time Error: File: *filename* Line: # Column: # The Compiler does not support EVAL or INPUT functions. Currently, these are unsupported functions.

Run-time Error: File: *filename* Line: # Column: # The function "*functionname*" was called with more than the declared number of inputs (*quantity1*). There is an inconsistency between the declared number of formal inputs and the actual number of inputs.
Run-time Error: File: filename Line: # Column: # The function "functionname" was called with more than the declared number of outputs (quantity1). There is an inconsistency between the declared number of formal outputs and the actual number of outputs.

Run-time Error: File: filename Line: # Column: # The load statement did not specifically list the names of variables to be loaded as constant strings. Use one of the forms of the load command that contains the names of the variables to be loaded, for example:

```
load filename num value
```

Run-time Error: File: filename Line: # Column: # The save statement did not specifically list the names of variables to be saved as constant strings. Use one of the forms of the save command that contains the names of the variables to be saved, for example:

```
save testdata num value
```
